1 Introduction

When writing functional code, we often use functions (or other datastructures) to ‘glue’ multiple pieces of data together. Take, as an example, the following function in the programming language Haskell, as introduced by [Gill et al. \(1993\)](#):

$$\begin{aligned} all &:: (a \rightarrow Bool) \rightarrow [a] \rightarrow Bool \\ all\ p &= and \circ map\ p \end{aligned}$$

The function `map p` traverses across the input list, applying the predicate `p` to each element, resulting in a new list of booleans. Then, the function `and` takes this resulting, intermediate, boolean list and consumes it by ‘anding’ together all the booleans.

Being able to compose functions in this fashion is part of what makes functional programming so attractive, but it comes at the cost of computational overhead: Each time allocating a list cell, only to subsequently deallocate it once the value has been read. We could instead rewrite `all` in the following fashion:

```
all' p xs = h xs
  where h [] = True
        h (x : xs) = p x ∧ h xs
```

This function, instead of traversing the input list, producing a new list, and then subsequently traversing that intermediate list, traverses the input list only once; immediately producing a new answer. Writing code in this fashion is far more performant, at the cost of read- and write-ability. Can you write a high-performance, single-traversal, version of the following function (Harper, 2011)?

```
f :: (Int, Int) → Int
f = sum ∘ map (+1) ∘ filter odd ∘ between
```

With some (more) effort and optimization, one could arrive at the following solution:

```
f' :: (Int, Int) → Int
f' (x, y) = loop x
  where loop x | x > y = 0
              | otherwise = if odd x
                           then (x + 1) + loop (x + 1)
                           else loop (x + 1)
```

Doing this by hand every time, to get from the nice, elegant, compositional style of programming to the higher-performance, single-traversal style, gets old very quick. Especially if this needs to be done, by hand, **every** time you compose any two functions. Is there some way to automate this process?

Fusion The answer is yes^{*}, but it comes with *an* asterisk attached. The form of optimization that we are looking for is called fusion: The process of taking multiple list producing/consuming functions and turning (or fusing) them into just one.

Initial work on this was done by Wadler (1984, 1986, 1990), and was dubbed ‘deforestation’, referring to the removal of intermediate trees (or lists). The details of the original deforestation work are not relevant to this thesis, but, the weaknesses of the work are described and a different technique are proposed by Gill et al. (1993). Gill et al. (1993) describe a technique nowadays called `foldr/build` fusion, which, when employed, can eliminate most intermediate lists. This technique is described further in Section 2.1.

A converse approach, aptly named the `destroy/unfoldr` rule, is described by Svenningsson (2002), which describes the converse technique to Gill et al. (1993)’s. A further generalization of this technique, leveraging the coinductive list datatype, streams. This technique ended up being called *stream fusion*.

(Co)Church encodings Finally, Harper (2011) combined all of these concepts into one paper, called “The Library Writer’s Guide to Shortcut Fusion”. In it the concept of (Co)Church encodings are described and, pragmatically, how to implement them in Haskell. My thesis is centered on Harper (2011)’s work and makes two crucial contributions:

1. The Church and Cochurch encodings described are formalized, including the relevant category theory, in Agda, in as a general fashion as possible, leveraging containers (Abbott et al., 2005) to represent strictly positive functors. Furthermore, the functions that are described (producing, transforming, and consuming) are also implemented in a general fashion and shown to be equal to regular folds (i.e. catamorphisms and anamorphisms). This is discussed in detail in Section 3.
2. The Church and Cochurch encodings’ implementation in Haskell, as described by Harper (2011) are replicated and investigated further as to their performance characteristics. In this process, a bug was found in Haskell’s optimizer, and further practical

insights were gleaned as to how to get these encodings to properly fuse as well (especially for Cochurch encodings) and what optimizations enable shortcut fusion to do its work. This is discussed in detail in Section 4.

Fusion, Category theory, Libfusion paper, church encodings, formalization of it, Haskell’s suite of optimizations that enable fusion, (theorems for free?).

2 Background

2.1 Foldr/build fusion (on lists)

Starting with the basics of fusion. In [Gill et al. \(1993\)](#)’s paper the original ‘shortcut deforestation’ technique was described. The core idea is described here as follows:

In functional programming lists are (often) used to store the output of one function such that it can then be consumed by another function. To co-opt [Gill et al. \(1993\)](#)’s example:

$$all\ p\ xs = and\ (map\ p\ xs)$$

`map p xs` applies `p` to all of the elements, producing a boolean list, and `and` takes that new list and “ands” all of them together to produce a resulting boolean value. “The intermediate list is discarded, and eventually recovered by the garbage collector” ([Gill et al., 1993](#)).

This generation and immediate consumption of an intermediate datastructure introduces a lot of computation overhead. Allocating resources for each `cons` datatype instance, storing the data inside of that instance, and then reading back that data, all take time. One could instead write the above function like this:

$$\begin{aligned} all'\ p\ xs &= h\ xs \\ \textbf{where}\ h\ [] &= True \\ h\ (x : xs) &= p\ x \wedge h\ xs \end{aligned}$$

Now no intermediate datastructure is generated at the cost of more programmer involvement. We’ve made a custom, specialized version of `and . map p`. The compositional style of programming that function programming languages enable (such as Haskell) would be made a lot more difficult if, for every composition, the programmer had to write a specialized function. Can this be automated?

[Gill et al. \(1993\)](#)’s key insight was to note that when using a `foldr k z xs` across a list, the effect of its application “is to replace each `cons` in the list `xs` with `k` and replace the `nil` in `xs` with `z`. By abstracting list-producing functions with respect to their connective datatype (`cons` and `nil`), we can define a function `build`:

$$build\ g = g\ (:) []$$

Such that:

$$foldr\ k\ z\ (build\ g) = g\ k\ z$$

[Gill et al. \(1993\)](#) dubbed this the `foldr/build` rule. For its validity `g` needs to be of type:

$$g : \forall \beta : (A \rightarrow \beta \rightarrow \beta) \rightarrow \beta \rightarrow \beta$$

Which can be proved to be true through the use of `g`’s free theorem à la [Wadler \(1989\)](#). For more information on free theorems see Section 2.4

2.1.1 An example

Take the function `from`, that takes two numbers and produces a list of all the numbers from the first to the second:

$$\begin{aligned} from\ a\ b &= \textbf{if}\ a > b \\ &\quad \textbf{then}\ [] \\ &\quad \textbf{else}\ a : from\ (a + 1)\ b \end{aligned}$$

To arrive at a suitable **g** we must abstract over the connective datatypes:

$$\begin{aligned} \text{from}' a b &= \lambda c n \rightarrow \text{if } a > b \\ &\quad \text{then } n \\ &\quad \text{else } c a (\text{from } (a + 1) b c n) \end{aligned}$$

This is obviously a different function, we now redefine **from** in terms of **build** (Gill et al., 1993):

$$\text{from } a b = \text{build } (\text{from}' a b)$$

With some inlining and β reduction, one can see that this definition is identical to the original **from** definition. Now for the killer feature (Gill et al., 1993):

$$\begin{aligned} \text{sum } (\text{from } a b) \\ &= \text{foldr } (+) 0 (\text{build } (\text{from}' a b)) \\ &= \text{from}' a b (+) 0 \end{aligned}$$

Notice how we can apply the **foldr/build** rule here to prevent an intermediate list being produced. Any adjacent **foldr/build** pair “cancel away”. This is an example of shortcut fusion.

One can rewrite many functions in terms of **foldr** and **build** such that this fusion can be applied. This can be seen in Figure 1. See Gill et al. (1993)’s work, specifically the end of section 3.3 (**unlines**) for a more expansive example of how fusion, β reduction, and inlining can combine to fuse a pipeline of functions down an as efficient minimum as can be expected.

$$\begin{aligned} \text{map } f \text{ } xs &= \text{build } (\lambda c n \rightarrow \text{foldr } (\lambda a b \rightarrow c (f a) b) n xs) \\ \text{filter } f \text{ } xs &= \text{build } (\lambda c n \rightarrow \text{foldr } (\lambda a b \rightarrow \text{if } f a \text{ then } c a b \text{ else } b) n xs) \\ xs \mathrel{++} ys &= \text{build } (\lambda c n \rightarrow \text{foldr } c (\text{foldr } c n ys) xs) \\ \text{concat } xs &= \text{build } (\lambda c n \rightarrow \text{foldr } (\lambda x Y \rightarrow \text{foldr } c y x) n xs) \\ \\ \text{repeat } x &= \text{build } (\lambda c n \rightarrow \text{let } r = c x r \text{ in } r) \\ \text{zip } xs \text{ } ys &= \text{build } (\lambda c n \rightarrow \text{let } \text{zip}' (x : xs) (y : ys) = c (x, y) (\text{zip}' xs ys) \\ &\quad \text{zip}' _ _ = n \\ &\quad \text{in } \text{zip}' xs ys) \\ \\ [] &= \text{build } (\lambda c n \rightarrow n) \\ x : xs &= \text{build } (\lambda c n \rightarrow c x (\text{foldr } c n xs)) \end{aligned}$$

Figure 1: Examples of functions rewritten in terms of **foldr/build**. (Gill et al., 1993)

2.1.2 Generalization to any datastructure

This is all well and good, when working with lists, that can be written in terms of **foldr**’s and/or **build**’s (which covers a lot of common functions already), but what if we want to do this for any data structure? Is there a way of generalizing this? The answer is yes*. *So long as the datatype we are working with is an initial algebra or terminal coalgebra, and the functions we are working with are instances of cata- or anamorphisms.

What does that even mean?

2.2 The category theory

In order to explain what an initial/terminal (co) algebra is, I’ll first need to explain what a functor is and, more pressingly, what a category is. The concept of cata- and anamorphisms will follow suit. If you’re familiar with category theory and these concepts, you can skip this section.

2.2.1 A Category

A **category** \mathcal{C} is a collection of four pieces of data satisfying three proofs:

1. A collection of objects, denoted by \mathcal{C}_0
2. For any given objects $X, Y \in \mathcal{C}_0$, a collection of morphisms from X to Y , denoted by $\text{hom}_{\mathcal{C}}(X, Y)$, which is called a *hom-set*.
3. For each object $X \in \mathcal{C}_0$, a morphism $\text{Id}_X \in \text{hom}_{\mathcal{C}}(X, X)$, called the *identity morphism* on X .
4. A binary operation: $(\circ)_{X,Y,Z} : \text{hom}_{\mathcal{C}}(Y, Z) \rightarrow \text{hom}_{\mathcal{C}}(X, Y) \rightarrow \text{hom}_{\mathcal{C}}(X, Z)$, called the *composition operator*, and written infix without the indices X, Y, Z as in $g \circ f$.

These pieces of data should satisfy the following three properties:

1. (**Left unit law**) For any morphism $f \in \text{hom}_{\mathcal{C}}(X, Y)$:

$$f \circ \text{Id}_X = f$$

2. (**Right unit law**) For any morphism $f \in \text{hom}_{\mathcal{C}}(X, Y)$:

$$\text{Id}_Y \circ f = f$$

3. (**Associative law**) For any morphisms $f \in \text{hom}_{\mathcal{C}}(X, Y), g \in \text{hom}_{\mathcal{C}}(Y, Z)$, and $h \in \text{hom}_{\mathcal{C}}(Z, W)$:

$$h \circ (g \circ f) = (h \circ g) \circ f$$

2.2.2 Initial/Terminal Objects

Categories can contain objects that have certain (useful) properties. Two of these properties are summarized below:

initial Let \mathcal{C} be a category. An object $A \in \mathcal{C}_0$ is **initial** if there is exactly one morphism from A to any object $B \in \mathcal{C}_0$:

$$\forall A, B \in \mathcal{C}_0 : \exists! \text{hom}_{\mathcal{C}}(A, B) \implies \text{initial}(A)$$

terminal Let \mathcal{C} be a category. An object $A \in \mathcal{C}_0$ is **terminal** if there is exactly one morphism from any object $B \in \mathcal{C}_0$ to A :

$$\forall A, B \in \mathcal{C}_0 : \exists! \text{hom}_{\mathcal{C}}(B, A) \implies \text{terminal}(A)$$

The proofs of initiality and terminality require a proof that is split into two steps: A proof of existence (The \exists part of $\exists!$) and a proof of uniqueness (The $!$ part of $\exists!$). The former is usually done by construction, giving an example of a function that satisfies the property and the latter is usually done by assuming that another $\text{hom}_{\mathcal{C}}(A, B)$ (for the initial case) exists and showing that it must be equal to the one constructed.

2.2.3 Functors

For a given category \mathcal{C}, \mathcal{D} , a **functor** from \mathcal{C} to \mathcal{D} consists of two pieces of data and three proofs:

1. A function mapping objects in \mathcal{C} to \mathcal{D} :

$$\mathcal{C}_0 \rightarrow \mathcal{D}_0$$

2. For each $X, Y \in \mathcal{C}_0$, a function mapping morphisms in \mathcal{C} to morphisms in \mathcal{D} :

$$\text{hom}_{\mathcal{C}}(X, Y) \rightarrow \text{hom}_{\mathcal{D}}(F(X), F(Y))$$

These pieces of data should satisfy these two properties:

1. (**Composition law**) for any two morphisms $f \in \text{hom}_{\mathcal{C}}(X, Y), g \in \text{hom}_{\mathcal{C}}(Y, Z)$:

$$F(g \circ f) = Fg \circ Ff$$

2. (**Identity law**) For any $X \in \mathcal{C}_0$, we have:

$$F(\text{Id}_X) = \text{Id}_{F(X)}$$

An **endofunctor** is a functor that maps objects back to the category itself, i.e. $F : \mathcal{C} \rightarrow \mathcal{C}$

2.2.4 (Category of) F-(Co)Algebras

Given an endofunctor $F : \mathcal{C} \rightarrow \mathcal{C}$:

An **F-Algebra** consists of two pieces of data:

1. An object $C \in \mathcal{C}_0$
2. A morphism $\phi \in \text{hom}_{\mathcal{C}}(F(C), C)$

An **F-Algebra Homomorphism** is, given two F-Algebras $(C, \phi), (D, \psi)$, a morphism $f \in \text{hom}_{\mathcal{C}}(C, D)$, such that the following diagram commutes (i.e. $f \circ \phi = \psi \circ Ff$):

$$\begin{array}{ccc} FC & \xrightarrow{\phi} & C \\ Ff \downarrow & & \downarrow f \\ FD & \xrightarrow{\psi} & D \end{array}$$

The **category of F-Algebras** denoted by $\mathcal{Alg}(F)$ consists of (the needed) four pieces of data:

1. The objects are F-Algebras
2. The morphisms are F-Algebra homomorphisms
3. The identity on (C, ϕ) is given by the identity Id_C in \mathcal{C}
4. The composition is given by the composition of morphisms in \mathcal{C}

These pieces of data should satisfy the usual category laws: left/right unit law and composition law. Note how $\mathcal{Alg}(F)$ makes use of the underlying category \mathcal{C} of the functor to define its objects. An $\mathcal{Alg}(F)$ implicitly contains an underlying category in which its objects are embedded.

An **F-Coalgebra** consists of two pieces of data:

1. An object $C \in \mathcal{C}_0$
2. A morphism $\phi \in \text{hom}_{\mathcal{C}}(C, F(C))$

F-Coalgebra homomorphisms and $\mathcal{CoAlg}(F)$ can be defined analogously as done for F-Algebras.

2.2.5 Cata- and Anamorphisms

Given (if it exists) an initial F-Algebra (μ^F, in) in $\mathcal{Alg}(F)$. We can know that (by definition), that for any other F-Algebra (C, ϕ) , there exists a *unique* morphism $\llbracket \phi \rrbracket \in \text{hom}_{\mathcal{C}}(\mu^F, C)$ such that the following diagram commutes:

$$\begin{array}{ccc} F\mu^F & \xrightarrow{\text{in}} & \mu^F \\ F\llbracket \phi \rrbracket \downarrow & & \downarrow \llbracket \phi \rrbracket \\ FC & \xrightarrow{\phi} & C \end{array}$$

A morphism of the form $\llbracket \phi \rrbracket$ is called a **catamorphism**.

An analogous definition of for terminal objects in $\mathcal{CoAlg}(F)$ exists, called **anamorphisms**, denoted by $\llbracket \phi \rrbracket$

2.2.6 Fusion property

Now for the definition we've been waiting for, **fusion**: Given an endofunctor $F : \mathcal{C} \rightarrow \mathcal{C}$ and an initial algebra (μ^F, in) in $\mathcal{Alg}(F)$. For any two F-Algebras (C, ϕ) and (D, ψ) and morphism $f \in \text{hom}_{\mathcal{C}}(C, D)$ we have a **fusion property**:

$$f \circ \phi = \psi \circ F(f) \implies f \circ \llbracket \phi \rrbracket = \llbracket \psi \rrbracket$$

In English, if f is an F-Algebra homomorphism, we can know that $f \circ \langle \psi \rangle = \langle \psi \rangle$. We can fuse two functions into one! This is summarized in the following diagram:

$$\begin{array}{ccc}
 F\mu^F & \xrightarrow{in} & \mu^F \\
 F\langle\phi\rangle \downarrow & & \downarrow \langle\phi\rangle \\
 FC & \xrightarrow{\phi} & C \\
 Ff \downarrow & & \downarrow f \\
 FD & \xrightarrow{\psi} & D
 \end{array}
 \begin{array}{l}
 \\
 \\
 \langle\psi\rangle \\
 \\
 \end{array}$$

An analogous definitions of fusion can be made for terminal object in $CoAlg(F)$

2.3 Library Writer's Guide to Shortcut Fusion

Gill et al. (1993)’s work has been built upon in several ways:

-

One work that attempts to clearly explain a generalized form of Gill et al. (1993)’s work is “A Library Writer’s Guide to Shortcut Fusion” by Harper (2011).

In the work, Harper (2011) explain the concept of Church and CoChurch encodings in three steps:

1. Explaining the mathematical background of Category theory, including F-Algebras, Fusion, and

2.4 Theorems for Free

2.5 Containers

3 Formalization

In Harper (2011)’s work “A Library Writer’s Guide to Shortcut Fusion”, the practice of implementing Church and CoChurch encodings is described, as well a paper proof necessary to show that the encodings optimizations employed are correct.

In this section the work I have done to formalize these proofs in the programming language Agda is discussed, as well as additional proofs to support the claims made in the paper.

The code can be neatly presented in roughly 2 parts:

- The proofs of the category theory truths described by [Harper \(2011\)](#).
- The proofs about the (Co)Church encodings, again as described by [Harper \(2011\)](#).

A note on imports: Imports are omitted in the agda code except when an import renames a construct it is importing, this is most prevalent for `Category`, `Data.W`, and `Container`.

3.1 Category Theory Formalization

3.1.1 funct

This module contains some simple definition, utilized in both complimentary structures (cata-/anamorphisms, church/cochurch).

Functional Extensionality We postulate functional extensionality. This is done through Agda's builtin Extensionality module:

```
module agda.funext.funext where
open import Axiom.Extensionality.Propositional
postulate funext : ∀{a b} → Extensionality a b
funexti : ∀{a b} → ExtensionalityImplicit a b
funexti = implicit-extensionality funext
```

Endofunctors An endofunctor is defined across the category of agda sets, where the functors are interpretations of containers. There is a little bit of unwieldiness as **Sets** defines equality through extensionality, but using an implicit parameter. In order to combine it with **funext** a little bit of unpacking and repacking of the definitions needs to be done.

```
module agda.funext.endo where
F[_] : (F : Container 0ℓ 0ℓ) → Endofunctor (Sets 0ℓ)
F[ F ] = record { F0 = [ F ]; F1 = map
; identity = refl ; homomorphism = refl
; F-resp-≈ = λ p → cong2 map (funext (λ x → p {x})) refl }
```

3.1.2 init

This module defines F-Algebras, a candidate initial object μ , and catamorphisms, and proves initiality of μ , the fusion properties, and the catamorphism laws.

Initial algebras and catamorphisms This module defines a function and shows it to be a catamorphism in the category of F-Algebras. Specifically, it is shown that $(\mu \text{ F}, \text{in}')$ is initial.

```
module agda.init.initialg where
open import Categories.Category renaming (Category to Cat)
open import Data.W using () renaming (sup to in')
```

A shorthand for the Category of F-Algebras.

```
C[_]Alg : (F : Container 0ℓ 0ℓ) → Cat (suc 0ℓ) 0ℓ 0ℓ
C[ F ]Alg = F-Algebras F[ F ]
```

A shorthand for an F-Algebra homomorphism:

```
_Alghom[_,_] : {X Y : Set} (F : Container 0ℓ 0ℓ) (x : [ F ] X → X) (Y : [ F ] Y → Y) → Set
F Alghom[ x , y ] = C[ F ]Alg [ to-Algebra x , to-Algebra y ]
```

A candidate function is defined, this will be proved to be a catamorphism through the proof of initiality:

```
(⌊_⌋) : {F : Container 0ℓ 0ℓ} {X : Set} → ([ F ] X → X) → μ F → X
(⌊ a ⌋) (in' (op , ar)) = a (op , ⌊ a ⌋ ∘ ar)
```

It is shown that any $(\lfloor _ \rfloor)$ is a valid F-Algebra homomorphism from in' to any other object **a**. This constitutes a proof of existence:

```
valid-falghom : {F : Container 0ℓ 0ℓ} {X : Set} (a : [ F ] X → X) → F Alghom[ in' , a ]
valid-falghom {X} a = record { f = ⌊ a ⌋ ; commutes = refl }
```

It is shown that any other valid F-Algebra homomorphism from in' to **a** is equal to the $(\lfloor _ \rfloor)$ function defined. This constitutes a proof of uniqueness:

```
isunique : {F : Container 0ℓ 0ℓ} {X : Set} {a : [ F ] X → X} (fhom : F Alghom[ in' , a ]) (x : μ F) →
⌊ a ⌋ x ≡ fhom .f x
```

```

isunique {_}{_}{a} fhom (in' (op , ar)) = begin
  (⟦ a ⟧ (in' (op , ar)))
≡⟨ -- Dfn of (⟦_⟧)
  a (op , (⟦ a ⟧ ∘ ar))
≡⟨ cong (λ h → a (op , h)) (funext $ isunique fhom ∘ ar) ⟩ -- induction
  a (op , (fhom .f) ∘ ar)
≡⟨ -- Dfn of map
  (a ∘ map (fhom .f)) (op , ar)
≡⟨ sym $ fhom .commutes ⟩
  (fhom .f ∘ in') (op , ar)
□

```

The two previous proofs, constituting a proof of existence and uniqueness, are combined to show that $(\mu \text{ F}, \text{in}')$ is initial:

```

initial-in : {F : Container 0ℓ 0ℓ} → IsInitial C[ F ]Alg (to-Algebra in')
initial-in = record { ! = λ {A} → valid-falghom (A .α)
                  ; !-unique = λ fhom {x} → isunique fhom x }

```

Initial F-Algebra fusion This module proves the categorical fusion property (see Section 2.2.6). From it, it extracts the ‘fusion law’ as it was declared by Harper (2011); which is easier to work with. This shows that the fusion law does follow from the fusion property.

```

module agda.init.fusion where
open import Categories.Category renaming (Category to Cat)

```

The categorical fusion property:

```

fusionprop : {F : Container 0ℓ 0ℓ}{A B μ : Set}{ϕ : ⟦ F ⟧ A → A}{ψ : ⟦ F ⟧ B → B}
  {init : ⟦ F ⟧ μ → μ}{i : IsInitial C[ F ]Alg (to-Algebra init)} →
  (f : F Alghom[ ϕ , ψ ]) → C[ F ]Alg [ i .! ≈ C[ F ]Alg [ f ∘ i .! ] ]
fusionprop {F} i f = i .!-unique (C[ F ]Alg [ f ∘ i .! ])

```

The ‘fusion law’:

```

fusion : {F : Container 0ℓ 0ℓ}{A B : Set}{a : ⟦ F ⟧ A → A}{b : ⟦ F ⟧ B → B}
  (h : A → B) → h ∘ a ≡ b ∘ map h → (⟦ b ⟧ ≡ h ∘ (⟦ a ⟧))
fusion h p = funext λ x → fusionprop initial-in (record { f = h ; commutes = λ {y} → cong-app p y }) {x}

```

Universal properties of catamorphisms This module proves some properties of catamorphisms.

```

module agda.init.initial where
open import Data.W using () renaming (sup to in')

```

The forward direction of the *universal property of folds* (Harper, 2011):

```

universal-propr : {F : Container 0ℓ 0ℓ}{X : Set}(a : ⟦ F ⟧ X → X)(h : μ F → X) →
  h ≡ (⟦ a ⟧ → h ∘ in' ≡ a ∘ map h)
universal-propr a h eq = begin
  h ∘ in'
≡⟨ cong (λ_ ∘ in') eq ⟩
  (⟦ a ⟧ ∘ in')
≡⟨
  a ∘ map (⟦ a ⟧)
≡⟨ cong (λ x → a ∘ map x) (sym eq) ⟩
  a ∘ map h
□

```

The *computation law* (Harper, 2011) (this is exactly how $\llbracket _ \rrbracket$ is defined in the first place):

```
comp-law : {F : Container 0ℓ 0ℓ}{A : Set}(a :  $\llbracket F \rrbracket A \rightarrow A$ ) → (a  $\llbracket \_ \rrbracket$  ∘ in' ≡ a ∘ map (a  $\llbracket \_ \rrbracket$ ))
comp-law a = refl
```

The *reflection law* (Harper, 2011):

```
reflection : {F : Container 0ℓ 0ℓ}(y :  $\mu F$ ) → (in'  $\llbracket \_ \rrbracket$  y ≡ y)
reflection (in' (op , ar)) = begin
  (in'  $\llbracket \_ \rrbracket$  (in' (op , ar)))
≡ ( -- Dfn of  $\llbracket \_ \rrbracket$  )
  in' (op , (in'  $\llbracket \_ \rrbracket$  ∘ ar))
≡ ( cong (λ x -> in' (op , x)) (funext (reflection ∘ ar)) )
  in' (op , ar)
□
```

```
reflection-law : {F : Container 0ℓ 0ℓ} → (in'  $\llbracket \_ \rrbracket$  ≡ id)
reflection-law {F} = funext (reflection {F})
```

3.1.3 term

This module defines F-CoAlgebras, a candidate terminal object ν , and anamorphisms, and proves terminality of ν , the fusion properties, and the anamorphism laws. This module is the compliment of `init`.

Terminal coalgebras and anamorphisms This module defines a datatype and shows it to be initial; and a function and shows it to be an anamorphism in the category of F-Coalgebras. Specifically, it is shown that (ν, out) is terminal.

```
{-# OPTIONS --guardedness #-}
module agda.term.termcoalg where
open import Categories.Category renaming (Category to Cat)
open import Data.Container using (Container; map) renaming ( $\llbracket \_ \rrbracket$  to  $\llbracket \_ \rrbracket$ )
```

A shorthand for the Category of F-Coalgebras:

```
C[_]CoAlg : (F : Container 0ℓ 0ℓ) → Cat (suc 0ℓ) 0ℓ 0ℓ
C[ F ]CoAlg = F-Coalgebras F[ F ]
```

A shorthand for an F-Coalgebra homomorphism:

```
_CoAlghom[_,_] : {X Y : Set}(F : Container 0ℓ 0ℓ)(x : X →  $\llbracket F \rrbracket X$ )(Y : Y →  $\llbracket F \rrbracket Y$ ) → Set
F CoAlghom[ x , y ] = C[ F ]CoAlg [ to-Coalgebra x , to-Coalgebra y ]
```

A candidate terminal datatype and anamorphism function are defined, they will be proved to be so later on this module:

```
record  $\nu$  (F : Container 0ℓ 0ℓ) : Set where
  coinductive
  field out :  $\llbracket F \rrbracket (\nu F)$ 
open  $\nu$ 
 $\llbracket \_ \rrbracket$  : {F : Container 0ℓ 0ℓ}{X : Set} → (X →  $\llbracket F \rrbracket X$ ) → X →  $\nu F$ 
out ( $\llbracket c \rrbracket$  x) = (λ (op , ar) → op ,  $\llbracket c \rrbracket$  ∘ ar) (c x)
```

Injectivity of the `out` constructor is postulated, I have not found a way to prove this, yet.

```
postulate out-injective : {F : Container 0ℓ 0ℓ}{x y :  $\nu F$ } → out x ≡ out y → x ≡ y
--out-injective eq = funext ?
```

It is shown that any $\llbracket _ \rrbracket$ is a valid F-Coalgebra homomorphism from `out` to any other object `a`. This constitutes a proof of existence:

```

valid-fcoalghom : {F : Container 0ℓ 0ℓ}{X : Set}(a : X → I[[ F ]] X) → F CoAlghom[ a , out ]
valid-fcoalghom {X} a = record { f = [[ a ]] ; commutes = refl }

```

It is shown that any other valid F-Coalgebra homomorphism from out to a is equal to the $[[_]]$ defined. This constitutes a proof of uniqueness. This uses out injectivity. SOMETHING ABOUT TERMINATION CHECKING.

```

{-# NON_TERMINATING #-}
isunique : {F : Container 0ℓ 0ℓ}{X : Set}{c : X → I[[ F ]] X}(fhom : F CoAlghom[ c , out ])
  (x : X) → [[ c ]] x ≡ fhom .f x
isunique {_-}{_-}{c} fhom x = out-injective (begin
  (out ∘ [[ c ]]) x
≡⟨ -- Definition of [[_-]]
  map [[ c ]] (c x)
≡⟨
  (λ(op , ar) → (op , [[ c ]] ∘ ar)) (c x)
-- Same issue as with the proof of reflection it seems...
≡⟨ cong (λ f → op , f) (funext $ isunique fhom ∘ ar) ⟩ -- induction
  (op , fhom .f ∘ ar)
≡⟨
  map (fhom .f) (c x)
≡⟨ -- Definition of composition
  (map (fhom .f) ∘ c) x
≡⟨ sym $ fhom .commutes ⟩
  (out ∘ fhom .f) x
□)
where op = Σ.proj₁ (c x)
      ar = Σ.proj₂ (c x)

```

The two previous proofs, constituting a proof of existence and uniqueness, are combined to show that $(\nu F, out)$

```

terminal-out : {F : Container 0ℓ 0ℓ} → IsTerminal C[ F ]CoAlg (to-Coalgebra out)
terminal-out = record { ! = λ {A} → valid-fcoalghom (A .α)
                      ; !-unique = λ fhom {x} → isunique fhom x }

```

Terminal F-Coalgebra fusion This module proves the categorical fusion property. From it, it extracts a ‘fusion law’ as it was defined by Harper (2011); which is easier to work with. This shows that the fusion law does follow from the fusion property.

```

{-# OPTIONS --guardedness #-}
module agda.term.cofusion where
open import Data.Container using (Container; map) renaming ([[_]] to I[[_]])

```

The categorical fusion property:

```

fusionprop : {F : Container 0ℓ 0ℓ}{C D ν : Set}{ϕ : C → I[[ F ]] C}{ψ : D → I[[ F ]] D}{term : ν → I[[ F ]] ν}
  (i : IsTerminal C[ F ]CoAlg (to-Coalgebra term))(f : F CoAlghom[ ψ , ϕ ]) →
  C[ F ]CoAlg [ i .! ≈ C[ F ]CoAlg [ i .! ∘ f ] ]
fusionprop {F} i f = i .!-unique (C[ F ]CoAlg [ i .! ∘ f ])

```

The ‘fusion law’:

```

fusion : {F : Container 0ℓ 0ℓ}{C D : Set}{c : C → I[[ F ]] C}{d : D → I[[ F ]] D}(h : C → D) →
  (d ∘ h ≡ map h ∘ c) → [[ c ]] ≡ [[ d ]] ∘ h
fusion h p = funext λ x → fusionprop terminal-out (record { f = h ; commutes = λ {y} → cong-app p y }) {x}

```

Universal property of anamorphisms This module proves some property of anamorphisms.

```
{-# OPTIONS --guardedness #-}
module agda.term.terminal where
open import Data.Container using (Container; map) renaming ([_] to I[_])
```

The forward direction of the *universal property of unfolds* Harper (2011):

```
universal-propr : {F : Container 0ℓ 0ℓ}{C : Set}{c : C → I[F] C}(h : C → ν F) →
  h ≡ [ c ] → out ∘ h ≡ map h ∘ c
universal-propr c h eq = begin
  out ∘ h
≡⟨ cong (λ _ → out) eq ⟩
  out ∘ [ c ]
≡⟨ ⟩
  map [ c ] ∘ c
≡⟨ cong (λ _ → c) (cong map (sym eq)) ⟩
  map h ∘ c
□
```

The *computation law* Harper (2011):

```
comp-law : {F : Container 0ℓ 0ℓ}{C : Set}(c : C → I[F] C) → out ∘ [ c ] ≡ map [ c ] ∘ c
comp-law c = refl
```

The *reflection law* Harper (2011): SOMETHING ABOUT TERMINATION.

```
{-# NON_TERMINATING #-}
reflection : {F : Container 0ℓ 0ℓ}(x : ν F) → [ out ] x ≡ x
reflection x = out-injective (begin
  out ([ out ] x)
≡⟨ ⟩
  map [ out ] (out x)
≡⟨ ⟩
  op , [ out ] ∘ ar
≡⟨ cong (λ f → op , f) (funext $ reflection ∘ ar) ⟩
  op , id ∘ ar
≡⟨ ⟩
  map id (out x)
≡⟨ ⟩
  out x
□)
where op = Σ.proj1 (out x)
      ar = Σ.proj2 (out x)
```

3.2 Short cut fusion

3.2.1 Church encodings

Definition of Church encodings This module defines Church encodings and the two conversions `con` and `abs`, called `toCh` and `fromCh` here, respectively. It also defines the generalized producing, transformation, and consuming functions, as described by Harper (2011).

```
module agda.church.defs where
open import Data.W using () renaming (sup to in')
```

The church encoding, leveraging containers:

```

data Church (F : Container 0ℓ 0ℓ) : Set1 where
  Ch : ({X : Set} → (⟦ F ⟧ X → X) → X) → Church F

```

The conversion functions:

```

toCh : {F : Container _ _} → μ F → Church F
toCh {F} x = Ch (λ {X : Set} → λ (a : ⟦ F ⟧ X → X) → ⟨ a ⟩ x)
fromCh : {F : Container 0ℓ 0ℓ} → Church F → μ F
fromCh (Ch g) = g in'

```

The generalized and encoded producing, transformation, and consuming functions, alongside proofs that they are equal to the functions they are encoding. First the producing function, this is a generalized version of [Gill et al. \(1993\)](#)’s `build` function:

```

prodCh : {F : Container _ _}{X : Set}(g : {Y : Set} → (⟦ F ⟧ Y → Y) → X → Y)(x : X) → Church F
prodCh g x = Ch (λ a → g a x)
eqprod : {F : Container _ _}{X : Set}{g : {Y : Set} → (⟦ F ⟧ Y → Y) → X → Y} →
  fromCh ∘ prodCh g ≡ g in'
eqprod = refl
-- This is something cool and extra and intermediate
transCh : {F G : Container _ _}(nat : {X : Set} → ⟦ F ⟧ X → ⟦ G ⟧ X) → Church F → Church G
transCh n (Ch g) = Ch (λ a → g (a ∘ n))
eqtrans : {F G : Container _ _}{nat : {X : Set} → ⟦ F ⟧ X → ⟦ G ⟧ X} →
  fromCh ∘ transCh nat ∘ toCh ≡ ⟨ in' ∘ nat ⟩
eqtrans = refl
-- This is foldr!
consCh : {F : Container _ _}{X : Set} → (c : (⟦ F ⟧ X → X)) → Church F → X
consCh c (Ch g) = g c
eqcons : {F : Container _ _}{X : Set}{c : (⟦ F ⟧ X → X)} →
  consCh c ∘ toCh ≡ ⟨ c ⟩
eqcons = refl

```

Proof obligations In ?’s work, five proofs are given for Church encodings. These are formalized in this module.

```

module agda.church.proofs where
open import Data.W using () renaming (sup to in')

```

The first proof proves that `fromCh ∘ toCh = id`, using the reflection law:

```

from-to-id : {F : Container 0ℓ 0ℓ} → fromCh ∘ toCh ≡ id
from-to-id {F} = funext (λ (x : μ F) → begin
  fromCh (toCh x)
≡⟨ -- Definition of toCh
  fromCh (Ch (λ {X : Set} → λ (a : ⟦ F ⟧ X → X) → ⟨ a ⟩ x))
≡⟨ -- Definition of fromCh
  (λ a → ⟨ a ⟩ x) in'
≡⟨ -- function application
  ⟨ in' ⟩ x
≡⟨ reflection x ⟩
  x
□)

```

The second proof is similar to the first, but it proves the composition in the other direction `toCh ∘ fromCh = id`. This proof leverages parametricity as described by [Wadler \(1989\)](#). It postulates the free theorem of the function `g`, to prove that “applying `g` to `b` and then passing the result to `h` is the same as just folding `c` over the datatype” ([Harper, 2011](#)):

```

postulate freetheorem-initial : {F : Container 0ℓ 0ℓ}{B C : Set}{b : ⟦ F ⟧ B → B}{c : ⟦ F ⟧ C → C}
  (h : B → C)(g : {X : Set} → (⟦ F ⟧ X → X) → X) →

```

$$h \circ b \equiv c \circ \text{map } h \rightarrow h (g \ b) \equiv g \ c$$

```

fold-invariance : {F : Container 0ℓ 0ℓ}{Y : Set}
  (g : {X : Set} → ([ F ] X → X) → X)(a : [ F ] Y → Y) →
  ([ a ]) (g in') ≡ g a
fold-invariance g a = freetheorem-initial ([ a ]) g refl
to-from-id : {F : Container 0ℓ 0ℓ}{g : {X : Set} → ([ F ] X → X) → X} →
  toCh (fromCh (Ch g)) ≡ Ch g
to-from-id {F}{g} = begin
  toCh (fromCh (Ch g))
≡⟨⟩ -- definition of fromCh
  toCh (g in')
≡⟨⟩ -- definition of toCh
  Ch (λ{X} a → ([ a ]) (g in'))
≡⟨ cong Ch (funexti λ{Y} → funext (fold-invariance g)) ⟩
  Ch g
□
to-from-id' : {F : Container 0ℓ 0ℓ} → toCh ∘ fromCh ≡ id
to-from-id' {F} = funext (λ where (Ch g) → to-from-id {F}{g})

```

The third proof shows that encoding functions constitute an implementation for the consumer functions being replaced:

```

cons-pres : {F : Container 0ℓ 0ℓ}{X : Set}(b : [ F ] X → X) →
  consCh b ∘ toCh ≡ ([ b ])
cons-pres {F} b = funext λ (x : μ F) → begin
  consCh b (toCh x)
≡⟨⟩ -- definition of toCh
  consCh b (Ch (λ a → ([ a ]) x))
≡⟨⟩ -- function application
  (λ a → ([ a ]) x) b
≡⟨⟩ -- function application
  ([ b ]) x
□

```

The fourth proof shows that producing functions constitute an implementation for the producing functions being replaced:

```

prod-pres : {F : Container 0ℓ 0ℓ}{X : Set}(f : {Y : Set} → ([ F ] Y → Y) → X → Y) →
  fromCh ∘ prodCh f ≡ f in'
prod-pres {F}{X} f = funext λ (s : X) → begin
  fromCh ((λ (x : X) → Ch (λ a → f a x)) s)
≡⟨⟩ -- function application
  fromCh (Ch (λ a → f a s))
≡⟨⟩ -- definition of fromCh
  (λ {Y : Set} (a : [ F ] Y → Y) → f a s) in'
≡⟨⟩ -- function application
  f in' s
□

```

The fifth, and final proof shows that conversion functions constitute an implementation for the conversion functions being replaced:

```

-- This last proofs could all use a rewrite, now that I've generalized the three different
trans-pred : {F G : Container 0ℓ 0ℓ} (f : {X : Set} → [ F ] X → [ G ] X) →
  fromCh ∘ transCh f ≡ ([ in' ∘ f ]) ∘ fromCh
trans-pred f = funext (λ where
  (Ch g) → (begin
    fromCh (transCh f (Ch g))
  ≡⟨⟩ -- Function application
    fromCh (Ch (λ a → g (a ∘ f))))

```

```

≡⟨ -- Definition of fromCh
  (λ a → g (a ∘ f)) in'
≡⟨ -- Function application
  g (in' ∘ f)
≡⟨ sym (fold-invariance g (in' ∘ f)) ⟩
  (in' ∘ f) (g in')
≡⟨ -- Definition of fromCh
  (in' ∘ f) (fromCh (Ch g))
□⟩)

```

3.2.2 Cochurch encodings

Definition of Cochurch encodings This module defines Cochurch encodings and the two conversion functions `con` and `abs`, called `toCoCh` and `fromCoCh` here, respectively. It also defines the generalized producing, transformation, and consuming functions, as described by Harper (2011). The definition of the CoChurch datatypes is defined slightly differently to how it is initially defined by Harper (2011). Instead an Isomorphic definition is used, whose type is described later on on the same page. The original definition is included as `CoChurch'`.

```

{-# OPTIONS --guardedness #-}
module agda.cochurch.defs where
open import Data.Container using (Container) renaming ([_] to I[_])

```

The Cochurch encoding, again leveraging containers:

```

data CoChurch (F : Container 0ℓ 0ℓ) : Set₁ where
  CoCh : {X : Set} → (X → I[F] X) → X → CoChurch F

```

The conversion functions:

```

toCoCh : {F : Container 0ℓ 0ℓ} → ν F → CoChurch F
toCoCh x = CoCh out x
fromCoCh : {F : Container 0ℓ 0ℓ} → CoChurch F → ν F
fromCoCh (CoCh h x) = I[h] x

```

The generalized encoded producing, transformation, and consuming functions, alongside the proof that they are equal to the functions they are encoding. First, the producing function, note that this is a generalized version of Svenningsson (2002)'s `unfoldr` function:

```

prodCoCh : {F : Container 0ℓ 0ℓ}{Y : Set} → (g : Y → I[F] Y) → Y → CoChurch F
prodCoCh g x = CoCh g x
eqprod : {F : Container 0ℓ 0ℓ}{Y : Set}{g : (Y → I[F] Y)} →
  fromCoCh ◦ prodCoCh g ≡ I[g]
eqprod = refl

```

Second the transformation function:

```

transCoCh : {F G : Container 0ℓ 0ℓ}(nat : {X : Set} → I[F] X → I[G] X) → CoChurch F → CoChurch G
transCoCh n (CoCh h s) = CoCh (n ◦ h) s
eqtrans : {F G : Container 0ℓ 0ℓ}{nat : {X : Set} → I[F] X → I[G] X} →
  fromCoCh ◦ transCoCh nat ◦ toCoCh ≡ I[nat ◦ out]
eqtrans = refl

```

Third the consuming function, note that this `a` is a generalized version of [Svenningsson \(2002\)](#)'s `destroy` function:

$$\begin{aligned} \text{consCoCh} &: \{F : \text{Container } 0l \ 0l\} \{Y : \text{Set}\} \rightarrow (c : \{S : \text{Set}\} \rightarrow (S \rightarrow \llbracket F \rrbracket S) \rightarrow S \rightarrow Y) \rightarrow \text{CoChurch } F \\ \text{consCoCh } c \ (\text{CoCh } h \ s) &= c \ h \ s \\ \text{eqcons} &: \{F : \text{Container } 0l \ 0l\} \{X : \text{Set}\} \{c : \{S : \text{Set}\} \rightarrow (S \rightarrow \llbracket F \rrbracket S) \rightarrow S \rightarrow X\} \rightarrow \\ &\quad \text{consCoCh } c \circ \text{toCoCh} \equiv c \ \text{out} \\ \text{eqcons} &= \text{refl} \end{aligned}$$

The original CoChurch definition is included here for completeness' sake, but it is not used elsewhere in the code.

```
data CoChurch (F : Container 0ℓ 0ℓ) : Set₁ where
  cochurch : (∃ λ S → (S → I[[ F ]] S) × S) → CoChurch' F
```

A mapping from `CoChurch'` to `CoChurch` and back is provided as well as a proof that their compositions are equal to the identity function, thereby proving isomorphism:

$$\begin{aligned} & \text{toConv} : \{F : \text{Container } _ \} \rightarrow \text{CoChurch}' F \rightarrow \text{CoChurch } F \\ & \text{toConv } (\text{cochurch } (S, (h, x))) = \text{CoCh } \{S\} \{h\} x \\ & \text{fromConv} : \{F : \text{Container } _ \} \rightarrow \text{CoChurch } F \rightarrow \text{CoChurch}' F \\ & \text{fromConv } (\text{CoCh } \{X\} h x) = \text{cochurch } ((X, h, x)) \\ & \text{to-from-conv-id} : \{F : \text{Container } 0\ell\ 0\ell\} \rightarrow \text{toConv} \circ \text{fromConv } \{F\} \equiv \text{id} \\ & \text{to-from-conv-id} = \text{funext } \lambda \text{ where} \\ & \quad (\text{CoCh } \{X\} h x) \rightarrow \text{refl} \\ & \text{from-to-conv-id} : \{F : \text{Container } 0\ell\ 0\ell\} \rightarrow \text{fromConv} \circ \text{toConv } \{F\} \equiv \text{id} \\ & \text{from-to-conv-id} = \text{funext } \lambda \text{ where} \\ & \quad (\text{cochurch } (S, (h, x))) \rightarrow \text{refl} \end{aligned}$$

4 Haskell Optimizations

In [Harper \(2011\)](#)'s work there were still multiple open questions left regarding the exact mechanics of what Church and Cochurch encodings did while making their way through the compiler. Why are Cochurch encodings faster in some pipelines, but slower in others? etc.

In this section I'll describe my work replicating the fused Haskell code of the [Harper \(2011\)](#)'s work and further optimization opportunities that were discovered along the way.

4.1 Church encodings

4.2 Cochurch encodings

5 Conclusion and Future Work

5.1 Future Work

- Strengthen Agda's typechecker wrt implicit parameters
- Strengthen Agda's termination checker wrt corecursive datastructures
- Implement (co)church-fused versions of Haskell's library functions.
- Investigate if creating a language that has this fusion built-in natively can be compiled more efficiently
- Look into leveraging parametricity with agda, so no `posulate`'s are needed.
