## 1 Introduction

When writing functional code, we often use functions (or other data structures) to 'glue' multiple pieces of data together. Take, as an example, the following function in the programming language Haskell, as introduced by Gill et al. (1993):

```
all :: (a \rightarrow Bool) \rightarrow [a] \rightarrow Bool

all \ p = and \circ map \ p
```

The function map p traverses across the input list, applying the predicate p to each element, resulting in a new boolean list. Then, the function and takes this resulting, intermediate, boolean list and consumes it by 'and-ing' together all the boolean values.

Being able to compose functions in this fashion is part of what makes functional programming so attractive, but it comes at the cost of computational overhead: Each time allocating a list cell, only to subsequently deallocate it once the value has been read. We could instead rewrite all in the following fashion:

```
all' \ p \ xs = h \ xs

where h \ [] = True

h \ (x : xs) = p \ x \wedge h \ xs
```

This function, instead of traversing the input list, producing a new list, and then subsequently traversing that intermediate list, traverses the input list only once; immediately producing a new answer. Writing code in this fashion is far more performant, at the cost of read- and write-ability. Can you write a high-performance, single-traversal, version of the following function (Harper, 2011)?

```
f :: (Int, Int) \to Int

f = sum \circ map (+1) \circ filter \ odd \circ between
```

With some (more) effort and optimization, one could arrive at the following solution:

```
\begin{split} f' &:: (Int, Int) \to Int \\ f' &:(x,y) = loop \ x \\ &\quad \text{where } loop \ x \mid x > y = 0 \\ &\quad | \ \text{otherwise} = \textbf{if} \ odd \ x \\ &\quad \quad \text{then} \ (x+1) + loop \ (x+1) \\ &\quad \quad \text{else} \ loop \ (x+1) \end{split}
```

Doing this by hand every time, to get from the nice, elegant, compositional style of programming to the higher-performance, single-traversal style, gets old very quick. Especially if this needs to be done, by hand, **every** time you compose any two functions. Is there some way to automate this process?

**Fusion** The answer is yes<sup>\*</sup>, but it comes with an asterisk attached, namely that the functions that we are working with a folds or unfolds. The form of optimization that we are looking for is called fusion: The process of taking multiple list producing/consuming functions and turning (or fusing) them into just one.

Much work already exists, which is discussed in detail in Section 5. My thesis will be focusing on a specific form of fusion called shortcut fusion through the use of (Co)Church encodings as described by Harper (2011).

My thesis centers on formalizing, replicating, and expanding upon Harper (2011)'s work and makes two crucial contributions:

1. The Church and Cochurch encodings described are formalized, including the relevant category theory, in Agda, in as a general fashion as possible, leveraging containers (Abbott et al., 2005) to represent strictly positive functors. Furthermore, the functions that are described (producing, transforming, and consuming) are also implemented in a general fashion and shown to be equal to regular folds (i.e., catamorphisms and anamorphisms).

This is important because there currently does not seem to exist a formalization of the work. Formally verifying the mathematics will strengthen the work done by Harper (2011), perhaps also aiding in understanding in how the different pieces of mathematics relate. This is discussed in detail in Section 3.

2. The Church and Cochurch encodings' implementation in Haskell, as described by Harper (2011) are replicated and investigated further as to their performance characteristics. In this process, a bug was found in Haskell's optimizer, and further practical insights were gleaned as to how to get these encodings to properly fuse as well (especially for Cochurch encodings) and what optimizations enable shortcut fusion to do its work.

This is important as Harper (2011) gave a good pragmatic explanation as to how to implement the (Co)Church encodings in Haskell, gave an example implementation, and benchmarked that implementation. He did not dive into too much detail as to why they work stating, "Interestingly, however, we note that Cochurch encodings consistently outperform Church encodings, sometimes by a significant margin. While we do consider these results conclusive, we think that these results merit further investigation." (Harper, 2011). This is what my research has (partially) set out to look into. This is discussed in detail in Section 4.

## 2 Background

Before discussing the work that I have done, it is important to describe the necessary background. My work builds on a body of existing work, namely foldr/build fusion (Gill et al., 1993), some category theory, Church encodings (Harper, 2011), Containers (Abbott et al., 2005), parametricity also known as free theorems Wadler (1989), and some optimizations in Haskell's optimization pipeline that are relevant for fusion.

I will be describing each of these works briefly. After that, in the next sections, I will describe the work that I have done that builds on these topics.

## 2.1 Foldr/build fusion (on lists)

Starting with the basics of fusion. In Gill et al. (1993)'s paper the original 'schortcut deforestation' technique was described. The core idea is described here as follows:

In functional programming lists are (often) used to store the output of one function such that it can then be consumed by another function. To co-opt Gill et al. (1993)'s example:

```
all \ p \ xs = and \ (map \ p \ xs)
```

map p xs applies p to all of the elements, producing a boolean list, and and takes that new list and "ands" all of them together to produce a resulting boolean value. "The intermediate list is discarded, and eventually recovered by the garbage collector" (Gill et al., 1993).

This generation and immediate consumption of an intermediate datastructure introduces a lot of computation overhead. Allocating resources for each cons datatype instance, storing the data inside of that instance, and then reading back that data, all take time. One could instead write the above function like this:

$$all' \ p \ xs = h \ xs$$
  
where  $h \ [] = True$   
 $h \ (x : xs) = p \ x \wedge h \ xs$ 

Now no intermediate datastructure is generated at the cost of more programmer involvement. We've made a custom, specialized version of and . map p. The compositional style of programming that function programming languages enable (such as Haskell) would be made a lot more difficult if, for every composition, the programmer had to write a specialized function. Can this be automated?

Gill et al. (1993)'s key insight was to note that when using a foldr k z xs across a list, the effect of its application "is to replace each cons in the list xs with k and replace the nil in xs with z. By abstracting list-producing functions with respect to their connective datatype (cons and nil), we can define a function build:

```
build g = g(:)
```

Such that:

```
foldr \ k \ z \ (build \ g) = g \ k \ z
```

Gill et al. (1993)."

Gill et al. (1993) dubbed this the foldr/build rule. For its validity g needs to be of type:

$$q: \forall \beta: (A \to \beta \to \beta) \to \beta \to \beta$$

Which can be proved to be true through the use of g's free theorem à la Wadler (1989). For more information on free theorems see Section 2.4

#### 2.1.1 An example

Take the function from, that takes two numbers and produces a list of all the numbers from the first to the second:

```
from a b = \mathbf{if} \ a > b

then []

else a : from (a + 1) b
```

To arrive at a suitable g we must abstract over the connective datatypes:

```
from' a b = \lambda c n \rightarrow \mathbf{if} a > b

then n

else c a (from (a + 1) b c n)
```

This is obviously a different function, we now redefine from in terms of build (Gill et al., 1993):

```
from \ a \ b = build \ (from' \ a \ b)
```

With some inlining and  $\beta$  reduction, one can see that this definition is identical to the original from definition. Now for the killer feature (Gill et al., 1993):

```
\begin{array}{l} sum \ (from \ a \ b) \\ = foldr \ (+) \ 0 \ (build \ (from' \ a \ b)) \\ = from' \ a \ b \ (+) \ 0 \end{array}
```

Notice how we can apply the foldr/build rule here to prevent an intermediate list being produced. Any adjacent foldr/build pair "cancel away". This is an example of shortcut fusion.

One can rewrite many functions in terms of foldr and build such that this fusion can be applied. This can be seen in Figure 1. See Gill et al. (1993)'s work, specifically the end of section 3.3 (unlines) for a more expansive example of how fusion,  $\beta$  reduction, and inlining can combine to fuse a pipeline of functions down an as efficient minimum as can be expected.

```
 map \ f \ xs = build \ (\lambda c \ n \to foldr \ (\lambda a \ b \to c \ (f \ a) \ b) \ n \ xs)   filter \ f \ xs = build \ (\lambda c \ n \to foldr \ (\lambda a \ b \to \mathbf{if} \ f \ a \ \mathbf{then} \ c \ a \ b \ \mathbf{else} \ b) \ n \ xs)   xs + ys = build \ (\lambda c \ n \to foldr \ c \ (foldr \ c \ n \ ys) \ xs)   concat \ xs = build \ (\lambda c \ n \to \mathbf{let} \ r = c \ x \ r \ \mathbf{in} \ r)   zip \ xs \ ys = build \ (\lambda c \ n \to \mathbf{let} \ zip' \ (x : xs) \ (y : ys) = c \ (x, y) \ (zip' \ xs \ ys)   zip' \ _- = n   \mathbf{in} \ zip' \ xs \ ys)   [] = build \ (\lambda c \ n \to n)   x : xs = build \ (\lambda c \ n \to c \ x \ (foldr \ c \ n \ xs))
```

Figure 1: Examples of functions rewritten in terms of foldr/build. (Gill et al., 1993)

#### 2.1.2 Generalization to any datastructure

This foldr/build fusion works for lists, but it has several limitations. One is that it only works on lists, this is alleviated using Church encodings and is described by Harper (2011). Secondly, the functions that we are writing need to be expressible in terms of compositions of foldrs and builds. What if we want to implement to converse approach? This exists and is destroy/unfoldr fusion and is described by Coutts et al. (2007). This work generalized by Cochurch encodings, also described by Harper (2011).

The generalization by Harper leverages (Co)Church, which uses definitions from category such as F-algebras and initiality. Don't know what they are? Read on in the next section, where I give these category theory definitions.

### 2.2 The category theory

In order to explain what an initial/terminal F-(co)algebra is, I'll first need to explain what a functor is and, more pressingly, what a category is. The concept of cata- and anamorphisms (folds and unfolds) will follow suit. If you're familiar with category theory and these concepts, you can skip this section.

#### 2.2.1 A Category

A **category** C is a collection of four pieces of data satisfying three proofs:

- 1. A collection of objects, denoted by  $\mathcal{C}_0$
- 2. For any given objects  $X, Y \in \mathcal{C}_0$ , a collection of morphisms from X to Y, denoted by  $hom_{\mathcal{C}}(X, Y)$ , which is called a *hom-set*.
- 3. For each object  $X \in \mathcal{C}_0$ , a morphism  $\mathrm{Id}_X \in \mathrm{hom}_{\mathcal{C}}(X,X)$ , called the *identity morphism* on X.
- 4. A binary operation:  $(\circ)_{X,Y,Z} : \hom_{\mathcal{C}}(Y,Z) \to \hom_{\mathcal{C}}(X,Y) \to \hom_{\mathcal{C}}(X,Z)$ , called the *composition operator*, and written infix without the indices X,Y,Z as in  $g \circ f$ .

These pieces of data should satisfy the following three properties:

1. (**Left unit law**) For any morphism  $f \in hom_{\mathcal{C}}(X,Y)$ :

$$f \circ \operatorname{Id}_X = f$$

2. (**Right unit law**) For any morphism  $f \in hom_{\mathcal{C}}(X,Y)$ :

$$\operatorname{Id}_Y \circ f = f$$

3. (Associative law) For any morphisms  $f \in hom_{\mathcal{C}}(X,Y), g \in hom_{\mathcal{C}}(Y,Z),$  and  $h \in hom_{\mathcal{C}}(Z,W)$ :

$$h \circ (q \circ f) = (h \circ q) \circ f$$

#### 2.2.2 Initial/Terminal Objects

Categories can contain objects that have certain (useful) properties. Two of these properties are summarized below:

initial Let  $\mathcal{C}$  be a category. An object  $A \in \mathcal{C}_0$  is initial if there is exactly one morphism from A to any object  $B \in \mathcal{C}_0$ :

$$\forall A, B \in \mathcal{C}_0 : \exists ! hom_{\mathcal{C}}(A, B) \Longrightarrow \mathbf{initial}(A)$$

**terminal** Let C be a category. An object  $A \in C_0$  is **terminal** if there is exactly one morphism from any object  $B \in C_0$  to A:

$$\forall A, B \in \mathcal{C}_0 : \exists ! hom_{\mathcal{C}}(B, A) \Longrightarrow \mathbf{terminal}(A)$$

The proofs of initality and terminality require a proof that is split into two steps: A proof of existence (The  $\exists$  part of  $\exists$ !) and a proof of uniqueness (The! part of  $\exists$ !). The former is usually done by construction, giving an example of a function that satisfies the property and the latter is usually done my assuming that another  $\mathsf{hom}_{\mathcal{C}}(A, B)$  (for the initial case) exists and showing that it must be equal to the one constructed.

## 2.2.3 Functors

For a given category  $\mathcal{C}, \mathcal{D}$ , a functor from  $\mathcal{C}$  to  $\mathcal{D}$  consists of two pieces of data and three proofs:

1. A function mapping objects in  $\mathcal{C}$  to  $\mathcal{D}$ :

$$\mathcal{C}_0 \to \mathcal{D}_0$$

2. For each  $X, Y \in \mathcal{C}_0$ , a function mapping morphisms in  $\mathcal{C}$  to morphisms in  $\mathcal{D}$ :

$$\hom_{\mathcal{C}}(X,Y) \to \hom_{\mathcal{D}}(F(X),F(Y))$$

These pieces of data should satisfy these two properties:

1. (Composition law) for any two morphisms  $f \in \text{hom}_{\mathcal{C}}(X,Y), g \in \text{hom}_{\mathcal{C}}(Y,Z)$ :

$$F(g \circ f) = Fg \circ Ff$$

2. (**Identity law**) For any  $X \in \mathcal{C}_0$ , we have:

$$F(\mathrm{Id}_X) = \mathrm{Id}_{F(X)}$$

An **endofunctor** is a functor that maps objects back to the category itself, i.e.  $F: \mathcal{C} \to \mathcal{C}$ 

## 2.2.4 (Category of) F-(Co)Algebras

Given an endofunctor  $F: \mathcal{C} \to \mathcal{C}$ :

An **F-Algebra** consists of two pieces of data:

- 1. An object  $C \in \mathcal{C}_0$
- 2. A morphism  $\phi \in hom_{\mathcal{C}}(F(C), C)$

An **F-Algebra Homomorphism** is, given two F-Algebras  $(C, \phi), (D, \psi)$ , a morphism  $f \in \text{hom}_{\mathcal{C}}(C, D)$ , such that the following diagram commutes (i.e.  $f \circ \phi = \psi \circ Ff$ ):

$$\begin{array}{ccc} FC & \stackrel{\phi}{\longrightarrow} C \\ Ff \downarrow & & \downarrow f \\ FD & \stackrel{\psi}{\longrightarrow} D \end{array}$$

The category of F-Algebras denoted by Alg(F) consists of (the needed) four pieces of data:

- 1. The objects are F-Algebras
- 2. The morphisms are F-Algebra homomorphisms
- 3. The identity on  $(C, \phi)$  is given by the identity  $Id_C$  in C
- 4. The composition is given by the composition of morphisms in C

These pieces of data should satisfy the usual category laws: left/right unit law and composition law. Note how  $\mathcal{A}lg(F)$  makes use of the underlying category  $\mathcal{C}$  of the functor to define its objects. An  $\mathcal{A}lg(F)$  implicitly contains an underlying category in which its objects are embedded.

6

An F-Coalgebra consists of two pieces of data:

- 1. An object  $C \in \mathcal{C}_0$
- 2. A morphism  $\phi \in hom_{\mathcal{C}}(C, F(C))$

F-Coalgebra homomorphisms and CoAlg(F) can be defined analogously as done for F-Algebras.

### 2.2.5 Cata- and Anamorphisms

Given (if it exists) an initial F-Algebra  $(\mu^F, in)$  in  $\mathcal{A}lg(F)$ . We can know that (by definition), that for any other F-Algebra  $(C, \phi)$ , there exists a unique morphism  $(\phi) \in \mathsf{hom}_{\mathcal{C}}(\mu^F, C)$  such that the following diagram commutes:

$$F\mu^{F} \xrightarrow{in} \mu^{F}$$

$$F(\phi) \downarrow \qquad \qquad \downarrow (\phi)$$

$$FC \xrightarrow{\phi} C$$

A morphism of the form  $(\phi)$  is called a **catamorphism**.

An analogous definition of for terminal objects in CoAlg(F) exists, called **anamorphisms**, denoted by  $\llbracket \phi \rrbracket$ 

#### 2.2.6 Fusion property

Now for the definition we've been waiting for, **fusion**: Given an endofunctor  $F: \mathcal{C} \to \mathcal{C}$  and an initial algebra  $(\mu^F, in)$  in  $\mathcal{A}lg(F)$ . For any two F-Algebras  $(C, \phi)$  and  $(D, \psi)$  and morphism  $f \in \mathsf{hom}_{\mathcal{C}}(C, D)$  we have a **fusion property**:

$$f\circ\phi=\psi\circ F(f)\Longrightarrow f\circ (\![\phi]\!]=(\![\psi]\!]$$

In English, if f is an F-Algebra homomorphism, we can know that  $f \circ (\psi) = (\psi)$ . We can fuse two functions into one! This is summarized in the following diagram:

$$F(\psi) \begin{pmatrix} F(\phi) \downarrow & & \mu^F \\ F(\phi) \downarrow & & \downarrow (\phi) \\ FC & \xrightarrow{\phi} & C \\ Ff \downarrow & & \downarrow f \\ FD & \xrightarrow{\psi} & D \end{pmatrix} (\psi)$$

An analogous definitions of fusion can be made for terminal object in CoAlg(F)

## 2.3 Library Writer's Guide to Shortcut Fusion

Now that the sufficient category theory has been explained, it is possible to describe Harper (2011)'s paper, which my thesis centers on called "A Library Writer's Guide to Shortcut Fusion".

In the work, Harper (2011) explain the concept of Church and CoChurch encodings in four steps: The necessary underlying category theory, the concepts of encodings and the proof obligations necessary for ensuring correctness of the encodings, the concepts of (Co)Church encodings with the proof of correctness, and finally an example implementation for leaf trees. I will now go through each step briefly.

#### 2.3.1 Category Theory

For the full overview of the category theory, see section 2.2.6. The main concepts that Harper (2011) explains are the *universal property of (un)folds*, the *fusion law*, and the *reflection law*; all of which can be derived from the category theory already described earlier.

The universal property of folds is as follows:

$$h = (a) \iff h \circ in = a \circ Fh$$

The fusion law as:

$$h \circ (a) = (b) \iff h \circ a = b \circ Fh$$

And the reflection law as:

$$(in) = id$$

I formalized and proved all of these properties in my Agda formalization. It is also interesting to note that, for the universal property of unfolds, the forward direction is the proof of existence and the backward direction the proof of uniqueness, for the proof of initiality of an algebra. Converse definitions exist for terminal coalgebras, but I will not cover them in this section. They do exist in my formalization.

#### 2.3.2 Encodings

The purpose of the encodings is to encode recursive functions, which are not inlined by Haskell's optimizer, into ones that are capable of being inlined and therefore fused: "For example, assume that we want to convert values of the recursive datatype  $\mu$ F to values of a type F. The idea is that C can faithfully represent values of  $\mu$ F, but composed functions over C can be fused automatically" (Harper, 2011).

Now, instead of writing functions over  $\mu F$ , we write functions over C, along with two conversion functions con:  $\mu F \to C$  (converst) and abs :  $C \to \mu F$  (abstract). In order for the datatype C to faithfully represent  $\mu F$ , we need  $abs \circ con = id_{\mu F}$ . I.e. that C can represent all values of  $\mu F$  uniquely.

In total there are four main proof obligations, the one mentioned above, as well as the commutation of the following three diagrams:

$$\mu F \xleftarrow{abs} C \qquad \qquad S \qquad \qquad \mu F \xrightarrow{con} C$$

$$f \downarrow \qquad \qquad \downarrow f_C \qquad \qquad p \downarrow \qquad \qquad \downarrow c_C$$

$$\mu F \xleftarrow{abs} C \qquad \qquad \mu F \xleftarrow{con} C$$

Where, in the second diagram, p is a producer function, generating a recursive data structure from a seed of type S, and, in the third diagram, c is a consumer function, consuming a recursive data structure to produce a value of type T.

#### 2.3.3 (Co)Church Encodings

Next, Harper (2011) proposes two encodings, Church and CoChurch.

Church is defined (abstractly) as the following datatype:

**data** Church 
$$F = Ch \ (\forall A \Rightarrow (F A \rightarrow A) \rightarrow A)$$

Church contains a recursion principle (often referred to as g throughout this thesis). With conversion and abstraction functions toCh and fromCh:

```
toCh :: mu \ F \rightarrow Church \ F

toCh \ x = Ch \ (\lambda a \rightarrow fold \ a \ x)

fromCh :: Church \ F \rightarrow mu \ F

fromCh \ (Ch \ g) = g \ \mathbf{in}
```

From these definitions, Harper proves the four proof obligations along with a fifth proof, proving the other composition of con and abs to be equal to id, thereby showing isomorphism. For the proof of transformers and con o abs = id, Harper makes use of the free theorem for the polymorphic recursion principle g. In all the five proofs for Church encodings, Harper does not use the fusion property.

**Cochurch** CoChurch is defined (abstractly) as the following datatype:

data 
$$CoChurch' F = \exists S \Rightarrow CoCh (S \rightarrow F S) S$$

An isomorphic definition which Harper later uses is the one I end up using in my formalization:

data 
$$CoChurch\ F = \forall\ S \Rightarrow CoCh\ (S \to F\ S)\ S$$

The Cochurch encoding encodes a coalgebra and a seed value together. The conversion and abstraction functions, toCoCh and fromCoCh:

```
toCoCh :: nu \ F \rightarrow CoChurch \ F

toCoCh \ x = CoCh \ out \ x

fromCoCh :: CoChurch \ F \rightarrow nu \ F

fromCoCh \ (CoCh \ h \ x) = unfold \ h \ x
```

Similarly to his description of Church encodings, Harper proves the four proof obligations as well as the additional fifth one. The  $con \circ abs = id$  proof, leverages the free theorem for the corecursion principle of the type CoChurch. The proof for natural transformations, however, does not use the free theorem and instead uses the fusion property for unfolds.

#### 2.3.4 Example implementation

To tie it all together, Harper gives an example implementation of how one would implement the encodings described so far. For this he uses Leaf Trees. He implements four functions, between, filter, concat, and sum, as a normal, recursive function, in Church encoded form, and in Cochurch encoded form.

In doing so, he shows exactly how one goes from using the normal, recursive datatypes and function that are typically used in Haskell, to Church and Cochurch encoded versions. To conclude the performance of different compositions of functions are compared to show the performance benefits and differences between the three different variants of functions.

## 2.4 Theorems for Free

Wadler (1989) in work 'Theorems for Free', describes a way of getting theorems from a polymorphic function only by looking at its type. In his paper, he uses the trick of reading types as relations (instead of sets) in order to derive a lemma called *parametricity*.

From this it is possible to derive a theorem that a type satisfies, without looking at its definition. These free theorems can be used to make claims about polymorphic functions. This is also done in Harper (2011)'s work; namely a theorem about the polymorphic induction principle and coinduction principle function types.

For example the free theorem of the following polymorphic function (Harper, 2011):

$$g: \forall A \circ (F A \to A) \to A$$

is the theorem stating that:

$$h \circ b = c \circ F \ h \Rightarrow h \ (g \ b) = g \ c$$

For functions  $b : F B \rightarrow B, c : F C \rightarrow C, h : B \rightarrow C.$ 

Within Agda, proving that the free theorems of the polymorphic function types are correct is something that is currently not possible without extensions. Recent work by Van Muylder et al. (2023) does exist, that extends cubical Agda with a --bridges extension that makes it possible to derive free theorems from within Agda. While it might be possible to leverage this implementation, the work is very new, having come out after the start of this thesis project. Instead, I have opted to postulate the free theorems needed, which is only on two locations.

#### 2.5 Containers

In my formalization I needed to represent functors somehow. While a RawFunctor datatype does exist, it does not provide the necessary structure such that proofs can be done over it, such as the functor laws.

Instead, I have opted to use Containers to represent strictly positive functors as described by Abbott et al. (2005). The definition of a container is as follows: ADFSDFSDFKJSDHFSDKLJHF These can be given a semantics (or extension) in the following manner: ADFSDFSDFKJSDHFSDKLJHF

The main benefit of leveraging containers to represent functions is that positivity is maintained as well as that the functor laws are true by definition. Deriving the container from a given (polynomial) functor is done in a couple of steps:

- 1. Analyze how many constructors your functor has, take as an example 2.
- 2. For the left side of the container take the coproduct of types that store the non-recursive subelements (such as const).
- 3. Count the amount of recursive elements in the constructor, the return type should include that many elements.

Taking an example:

	List	Binary Tree
Base functor	$F_A X := 1 + (A \times X)$	$F_A X := 1 + (X \times A \times X)$
Left container half	Fin 1 + const A	Fin 1 + const A
Right container half	$\mathtt{nil}   o  \mathtt{Fin}   \mathtt{0}   \mathtt{and}   \mathtt{const}   \mathtt{n}   o  \mathtt{Fin}   \mathtt{1}$	$\mathtt{nil}   o  \mathtt{Fin}   \mathtt{0}   \mathtt{and}   \mathtt{const}   \mathtt{n}   o  \mathtt{Fin}   \mathtt{2}$

List Taking the base functor for List:  $F_A X := 1 + A \times X$ .

For the left side we take the coproduct of Fin 1 and const A, corresponding to the 'nil' and 'cons a \_' part, respectively.

For the right side, we have one constructor that is non-recursive and one that contains one recursive element, so we have:  $0 \to \text{Fin } 0$  and  $\text{const } n \to \text{Fin } 1$ . The Fin 1 refers to the recursive X that is present in the base functor (or the 'cons\_ as' part of cons).

Binary tree Taking the base functor for Tree:  $F_A$  X := 1 + X  $\times$  A  $\times$  X.

For the left side we take the coproduct of Fin 1 and const A.

For the right side, we have one constructor that is non-recursive and one that contains two recursive elements, so we have:  $0 \rightarrow \text{Fin } 0$  and  $\text{const } n \rightarrow \text{Fin } 2$ .

## 2.6 Haskell's optimization pipeline

In order to understand how fusion works, it is important to understand a few other concepts that fusion works in tandem with. Namely, beta reduction, inlining, case-of-case, and tail call optimization. I will give a brief description of each.

#### 2.6.1 Beta reduction

Beta reduction is simply the rule where an expression of the form  $(\lambda \ x \ . \ a[x])$  y can get transformed into a[y]. For example  $(\lambda \ x \ . \ x + x)$  y would become y + y.

#### 2.6.2 Inlining

Inlining is the process of taking a function expression and unfolding it into its definition. If we take the function f = (+2) and an expression f = (+2) and an expression f = (+2) and inline again to obtain f = (+2) and in the function f = (+2) and f = (+2) and f = (+2) are taken the function f = (+2) and f = (+2) and f = (+2) are taken f = (+2) and f = (+2) and f = (+2) and f = (+2) are taken f = (+2) and f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) are taken f = (+2) and f = (+2) are taken f = (+2) are taken f = (+2) are taken f = (+2) and f = (+2) are taken f

## 2.6.3 Case of case

TODODOD

#### 2.6.4 Tail call optimization

We call a recursive function tail-recursive, if all its recursive calls are returned immediately upon completion i.e., they don't do any additional calculations upon the result of the recursive call before returning a result.

When a function is tail-recursive, it is possible to reuse the stack frame of the current function call, reducing a lot of memory overhead. Haskell is able to identify tail-recursive functions and optimize the compiled byte code accordingly.

#### 3 Formalization

In Harper (2011)'s work "A Library Writer's Guide to Shortcut Fusion", the practice of implementing Church and CoChurch encodings is described, as well a paper proof necessary to show that the encodings optimizations employed are correct.

In this section the work I have done to formalize these proofs in the programming language Agda is discussed, as well as additional proofs to support the claims made in the paper.

The code can be neatly presented in roughly 2 parts:

- The proofs of the category theory truths described by Harper (2011).
- The proofs about the (Co)Church encodings, again as described by Harper (2011).

#### 3.1 Category Theory Formalization

This section is about my formalization of Harper (2011)'s work that describes the needed category theory, to be leveraged later on in the fusion part of the formalization.

#### 3.1.1 init

This module defines the category of F-Algebras, initiality of  $\mu$ , the universal properties of folds, and the fusion properties.

Universal properties of catamorphisms and initiality This module defines a function and shows it to be a catamorphism in the category of F-Agebras, by module proving some properties of catamorphisms and is showing that ( $\mu$  F, in') is initial.

```
module agda.init.initial where open import Data.W using () renaming (sup to in'; foldr to (_)) public
```

A shorthand for the Category of F-Algebras.

```
C[_]Alg : (F: \mathsf{Container} \ 0\ell \ 0\ell) \to \mathsf{Cat} \ (\mathsf{Isuc} \ 0\ell) \ 0\ell \ 0\ell
C[ F ]Alg = F-Algebras F[ F ]
```

A candidate function is defined, this will be proved to be a catamorphism through the proof of initiality:

```
--(_) : {F : Container 0$\ell$ 0$\ell$}{X : Set} \rightarrow ([ F ] X \rightarrow X) \rightarrow \mu$ F \rightarrow X \rightarrow (in' (op , ar)) = a (op , ( a ) \circ ar)
```

It is shown that any () is a valid F-Algebra homomorphism from in' to any other object a; i.e. the forward direction of the *universal property of folds* (Harper, 2011). This constitutes a proof of existence:

```
univ-to : \{F: \mathsf{Container} \ \mathsf{O}\ell \ \mathsf{O}\ell\} \{X: \mathsf{Set}\} \{a: \llbracket F \rrbracket \ X \to X\} \{h: \mu \ F \to X\} \to h \equiv ( \mid a \mid) \to h \circ \mathsf{in'} \equiv a \circ \mathsf{map} \ h univ-to refl = refl
```

It is shown that any other valid F-Algebra homomorphism from in' to a is equal to the (1) function defined; i.e. the backwards direction of the *universal property of folds* (Harper, 2011). This constitutes a proof of uniqueness:

```
 \begin{array}{l} \text{univ-from}: \ \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \{X: \mathsf{Set}\} (a: \llbracket F \rrbracket \ X \to X) (h: \mu \ F \to X) \to \\ h \circ \mathsf{in'} \equiv a \circ \mathsf{map} \ h \to (x: \mu \ F) \to h \ x \equiv ( \parallel a \parallel ) \ x \\ \\ \mathsf{univ-from} \ a \ h \ eq \ (\mathsf{in'} \ x @ (op \ , ar)) = \mathsf{begin} \\ (h \circ \mathsf{in'}) \ x \\ \equiv \langle \mathsf{cong-app} \ eq \ x \ \rangle \\ (a \circ \mathsf{map} \ h) \ x \\ \equiv \langle \rangle \\ a \ (op \ , h \circ ar) \\ \equiv \langle \mathsf{cong} \ (\lambda \ f \to a \ (op \ , f)) \ (\mathsf{funext} \ \$ \ \mathsf{univ-from} \ a \ h \ eq \circ ar) \ \rangle \\ a \ (op \ , ( \parallel a \ ) \circ ar) \\ \equiv \langle \rangle \\ (a \circ \mathsf{map} \ ( \parallel a \ ) ) \ x \\ \equiv \langle \rangle \\ (( \parallel a \ ) \circ \mathsf{in'}) \ x \\ \end{array}
```

The two previous proofs, constituting a proof of existence and uniqueness, are combined to show that ( $\mu$  F, in') is initial:

```
 \begin{array}{l} \text{initial-in}: \; \{F: \mathsf{Container} \; 0\ell \; 0\ell\} \to \mathsf{IsInitial} \; \mathsf{C}[\; F \;] \mathsf{Alg} \; (\mathsf{to-Algebra} \; \mathsf{in'}) \\ \mathsf{initial-in} = \mathsf{record} \; \{\; ! \; = \; \lambda \; \{A\} \to \\ & \mathsf{record} \; \{ \\ & \mathsf{f} \; = \; \emptyset \; \alpha \; A \; \emptyset \\ & ; \; \mathsf{commutes} \; = \; \lambda \; \{x\} \to \mathsf{cong-app} \; (\mathsf{univ-to} \; \{ \_ \} \{ \_ \} \{ \alpha \; A \} \; \mathsf{refl}) \; x \; \} \\ ; \; \mathsf{!-unique} \; = \; \lambda \; \{A\} \; \mathit{fhom} \; \{x\} \to \mathsf{sym} \; \$ \; \mathsf{univ-from} \; (\alpha \; A) \; (\mathsf{f} \; \mathit{fhom}) \; (\mathsf{funext} \; (\lambda \; y \to \mathsf{commutes} \; \mathit{fhom}) \; \} \\ \end{aligned}
```

The computation law (Harper, 2011):

```
 \begin{array}{l} \operatorname{comp-law}: \ \{F: \operatorname{Container} \ 0\ell \ 0\ell \} \{A: \operatorname{Set}\} (a: \ \llbracket \ F \ \rrbracket \ A \to A) \to ( \ a \ ) \circ \operatorname{in'} \equiv a \circ \operatorname{map} ( \ a \ ) \circ \operatorname{comp-law} \ a = \operatorname{refl} \end{array} )  The \operatorname{reflection} \operatorname{law} \ (\operatorname{Harper}, \ 2011):  \begin{array}{l} \operatorname{reflection}: \ \{F: \operatorname{Container} \ 0\ell \ 0\ell \} (y: \mu \ F) \to ( \operatorname{in'} \ ) \ y \equiv y \\ \operatorname{reflection} y @ (\operatorname{in'} \ (op \ , ar)) = \operatorname{begin} \\ ( \ \operatorname{in'} \ ) \ y \\ \equiv \langle \rangle \ -- \ \operatorname{Dfn} \ \operatorname{of} \ ( \cup ) \\ \operatorname{in'} \ (op \ , ( \operatorname{in'} \ ) \circ ar) \\ \equiv \langle \operatorname{cong} \ (\lambda \ x \to \operatorname{in'} \ (op \ , x)) \ (\operatorname{funext} \ (\operatorname{reflection} \circ ar)) \ \rangle \\ y \\ \blacksquare  \end{array}   \begin{array}{l} \operatorname{reflection-law}: \ \{F: \operatorname{Container} \ 0\ell \ 0\ell \} \to ( \operatorname{in'} \ ) \equiv \operatorname{id} \\ \operatorname{reflection-law} \ \{F\} = \operatorname{funext} \ (\operatorname{reflection} \ \{F\}) \end{array}
```

Initial F-Algebra fusion This module proves the categorical fusion property (see Section 2.2.6). From it, it extracts the 'fusion law' as it was declared by Harper (2011); which is easier to work with. This shows that the fusion law does follow from the fusion property.

```
module agda.init.fusion where
```

The categorical fusion property:

```
 \begin{array}{l} \text{fusionprop}: \ \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \{A \ B \ \mu: \mathsf{Set}\} \{\phi: \llbracket \ F \ \rrbracket \ A \to A\} \{\psi: \llbracket \ F \ \rrbracket \ B \to B\} \\ \{init: \llbracket \ F \ \rrbracket \ \mu \to \mu\} (i: \mathsf{IsInitial} \ \mathsf{C}[\ F \ \mathsf{]Alg} \ (\mathsf{to-Algebra} \ init)) \to \\ (f: \mathsf{C}[\ F \ \mathsf{]Alg} \ [\ \mathsf{to-Algebra} \ \phi \ , \ \mathsf{to-Algebra} \ \psi \ ]) \to \mathsf{C}[\ F \ \mathsf{]Alg} \ [\ i: ! \approx \mathsf{C}[\ F \ \mathsf{]Alg} \ [\ f \circ i: ! \ ] \ ] \\ \mathsf{fusionprop} \ \{F\} \ i \ f = i: !\text{-unique} \ (\mathsf{C}[\ F \ \mathsf{]Alg} \ [\ f \circ i: ! \ ]) \\ \end{array}
```

The 'fusion law':

```
fusion : \{F: \mathsf{Container}\ 0\ell\ 0\ell\} \{A\ B: \mathsf{Set}\} \{a: \llbracket\ F\ \rrbracket\ A \to A\} \{b: \llbracket\ F\ \rrbracket\ B \to B\} \ (h: A \to B) \to h \circ a \equiv b \circ \mathsf{map}\ h \to (b) \equiv h \circ (a) \ \mathsf{fusion}\ h\ p = \mathsf{funext}\ \lambda\ x \to \mathsf{fusionprop}\ \mathsf{initial-in}\ (\mathsf{record}\ \{\ f = h\ ;\ \mathsf{commutes} = \lambda\ \{y\} \to \mathsf{cong-app}\ p\ y\ \})\ \{x\}
```

#### 3.1.2 term

This module defines the category of F-CoAlgebras, a candidate terminal object  $\nu$ , anamorphisms, proves terminality of  $\nu$ , the universal properties of unfolds, and the fusion properties. This module is the compliment of init.

**Terminal coalgebras and anamorphisms** This module defines a datatype and shows it to be initial; and a function and shows it to be an anamorphism in the category of F-Coalgebras. Specifically, it is shown that  $(\nu, \text{ out})$  is terminal.

```
{-# OPTIONS --guardedness #-} module agda.term.terminal where open import Agda.Builtin.Sigma public open import Level using (0\ell; Level) renaming (suc to Isuc) public open import Data.Container using (Container; [_]; map; _{\sim}) public open import Function using (_{\sim}; _{\sim}; id; const) public open import Relation.Binary.PropositionalEquality as Eq using (_{\sim}; refl; sym; cong; cong-app; subst) public open Eq.=-Reasoning public
```

A shorthand for the Category of F-Coalgebras:

```
C[_]CoAlg : (F : Container \ 0\ell \ 0\ell) \rightarrow Cat \ (Isuc \ 0\ell) \ 0\ell \ 0\ell
C[ F ]CoAlg = F-Coalgebras F[ F ]
```

A candidate terminal datatype and anamorphism function are defined, they will be proved to be so later on this module:

```
out: \{F: \mathsf{Container}\ 0\ell\ 0\ell\} \to \nu\ F \to \llbracket F\ \rrbracket \ (\nu\ F) out nu = \mathsf{head}\ nu, tail nu = \mathsf{Los}\ \{F: \mathsf{Container}\ 0\ell\ 0\ell\} \{X: \mathsf{Set}\} \to (\mathsf{X} \to \llbracket F\ \rrbracket\ \mathsf{X}) \to \mathsf{X} \to \nu\ \mathsf{F} \to \mathsf{Los}\ \mathsf{Los}\
```

It is shown that any [] is a valid F-Coalgebra homomorphism from out to any other object a; i.e. the forward direction of the *universal property of unfolds* Harper (2011). This constitutes a proof of existence:

```
univ-to : \{F: \mathsf{Container}\ 0\ell\ 0\ell\} \{C: \mathsf{Set}\} (h:C \to \nu\ F) \{c:C \to \llbracket\ F\ \rrbracket\ C\} \to h \equiv \mathsf{A}\llbracket\ c\ \rrbracket \to \mathsf{out} \circ h \equiv \mathsf{map}\ h \circ c univ-to _ refl = refl
```

Injectivity of the out constructor is postulated, I have not found a way to prove this, yet.

```
postulate out-injective : \{F: \text{Container } 0\ell \ 0\ell\}\{x \ y: \nu \ F\} \to \text{out } x \equiv \text{out } y \to x \equiv y -\text{out-injective eq} = \text{funext } ?
```

It is shown that any other valid F-Coalgebra homomorphism from out to a is equal to the [] defined; i.e. the backward direction of the *universal property of unfolds* Harper (2011). This constitutes a proof of uniqueness. This uses out injectivity. Currently, Agda's termination checker does not seem to notice that the proof in question terminates:

The two previous proofs, constituting a proof of existence and uniqueness, are combined to show that ( $\nu$  F, out) is terminal:

```
 \begin{array}{l} \text{terminal-out}: \left\{F: \mathsf{Container} \ 0\ell \ 0\ell\right\} \to \mathsf{IsTerminal} \ \mathsf{C}[\ F\ ] \mathsf{CoAlg} \ (\mathsf{to-Coalgebra} \ \mathsf{out}) \\ \mathsf{terminal-out} = \mathsf{record} \ \left\{\begin{array}{l} ! = \lambda \ \{A\} \to \mathsf{record} \ \left\{\begin{array}{c} \mathsf{f} \\ \mathsf{f} = \mathsf{A} \llbracket \ \alpha \ A \ \rrbracket \\ ; \ \mathsf{commutes} = \lambda \ \{x\} \to \mathsf{cong-app} \ (\mathsf{univ-to} \ \mathsf{A} \llbracket \ \alpha \ A \ \rrbracket \ \{\alpha \ A\} \ \mathsf{refl}) \ x \ \right\} \\ \mathsf{;} \ \mathsf{!-unique} = \lambda \ \{A\} \ \mathit{fhom} \ \{x\} \to \mathsf{sym} \ (\mathsf{univ-from} \ (\mathsf{f} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{fhom}) \ \{\alpha \ A\} \ (\mathsf{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathit{funext} \ (\lambda \ y \to \mathsf{commutes} \ \mathsf{funext} \ (\lambda \ \mathsf{f
```

The computation law Harper (2011):

```
 \text{computation-law}: \{F: \mathsf{Container} \ 0\ell \ 0\ell \} \{C: \mathsf{Set}\} (c: C \to \llbracket F \rrbracket \ C) \to \mathsf{out} \circ \mathsf{A} \llbracket \ c \ \rrbracket \equiv \mathsf{map} \ \mathsf{A} \llbracket \ c \ \rrbracket \circ c \mathsf{computation-law} \ c = \mathsf{refl}
```

The reflection law Harper (2011): SOMETHING ABOUT TERMINATION.

**Terminal F-Coalgebra fusion** This module proves the categorical fusion property. From it, it extracts a 'fusion law' as it was defined by Harper (2011); which is easier to work with. This shows that the fusion law does follow from the fusion property.

```
{-# OPTIONS --guardedness #-} module agda.term.cofusion where
```

The categorical fusion property:

```
 \begin{array}{l} \text{fusionprop}: \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \{C \ D \ \nu: \mathsf{Set}\} \\ \qquad \qquad \{\phi: \ C \to \llbracket \ F \ \rrbracket \ C\} \{\psi: \ D \to \llbracket \ F \ \rrbracket \ D\} \{term: \nu \to \llbracket \ F \ \rrbracket \ \nu\} \\ \qquad \qquad (i: \mathsf{IsTerminal} \ \mathsf{C}[\ F \ ] \mathsf{CoAlg} \ (\mathsf{to-Coalgebra} \ term)) (f: \mathsf{C}[\ F \ ] \mathsf{CoAlg} \ [\ \mathsf{to-Coalgebra} \ \psi \ , \ \mathsf{to-Coalgebra} \ \phi \ ]) \to \mathsf{C}[\ F \ ] \mathsf{CoAlg} \ [\ i:! \circ f \ ] \ ] \\ \mathsf{fusionprop} \ \{F\} \ if = i: !\text{-unique} \ (\mathsf{C}[\ F \ ] \mathsf{CoAlg} \ [\ i:! \circ f \ ]) \end{array}
```

The 'fusion law':

## 3.2 Short cut fusion

This section focuses on the fusion of Church and Cochurch encodings, leveraging parametricity (free theorems) and the fusion property.

#### 3.2.1 Church encodings

This section describes the church-encodings and the proofs needed for the fusion property.

**Definition of Church encodings** This module defines Church encodings and the two conversions con and abs, called toCh and fromCh here, respectively. It also defines the generalized producing, transformation, and consuming functions, as described by Harper (2011).

```
module agda.church.defs where
```

The church encoding, leveraging containers:

```
data Church (F: \mathsf{Container} \ 0\ell \ 0\ell): \mathsf{Set}_1 \ \mathsf{where} \mathsf{Ch}: (\{X: \mathsf{Set}\} \to (\llbracket F \rrbracket \ X \to X) \to X) \to \mathsf{Church} \ F
```

The conversion functions:

```
\begin{array}{l} \operatorname{toCh}: \{F: \operatorname{Container} \ \_\ \} \to \mu \ F \to \operatorname{Church} \ F \\ \operatorname{toCh} \ \{F\} \ x = \operatorname{Ch} \ (\lambda \ \{X: \operatorname{Set}\} \to \lambda \ (a: \llbracket F \rrbracket \ X \to X) \to ( a \ ) \ x) \\ \operatorname{fromCh}: \{F: \operatorname{Container} \ \_\ \} \to \operatorname{Church} \ F \to \mu \ F \\ \operatorname{fromCh} \ (\operatorname{Ch} \ g) = g \ \operatorname{in'} \end{array}
```

The generalized and encoded producing, transformation, and consuming functions, alongside proofs that they are equal to the functions they are encoding. First the producing function, this is a generalized version of Gill et al. (1993)'s build function:

```
\begin{array}{l} \operatorname{prodCh}: \ \{\ell: \operatorname{Level}\}\{F: \operatorname{Container} \ \_\ \_\}\{Y: \operatorname{Set} \ell\} \\ \qquad (g: \{X: \operatorname{Set}\} \to (\llbracket F \rrbracket \ X \to X) \to Y \to X)(y: Y) \to \operatorname{Church} \ F \\ \operatorname{prodCh} \ g \ x = \operatorname{Ch} \ (\lambda \ a \to g \ a \ x) \\ \\ \operatorname{prod}: \ \{\ell: \operatorname{Level}\}\{F: \operatorname{Container} \ \_\ \_\}\{Y: \operatorname{Set} \ell\} \\ \qquad (g: \{X: \operatorname{Set}\} \to (\llbracket F \rrbracket \ X \to X) \to Y \to X)(y: Y) \to \mu \ F \\ \operatorname{prod} \ g = \operatorname{fromCh} \circ \operatorname{prodCh} \ g \\ \\ \operatorname{eqProd}: \ \{F: \operatorname{Container} \ \_\ \_\}\{Y: \operatorname{Set}\} \\ \qquad \{g: \{X: \operatorname{Set}\} \to (\llbracket F \rrbracket \ X \to X) \to Y \to X\} \to \operatorname{prod} \ g \equiv g \ \operatorname{in'} \\ \operatorname{eqProd} = \operatorname{refl} \end{array}
```

Second, the natural transformation function:

Third, the consuming function, note that this is a generalized version of Gill et al. (1993)'s foldr function.

```
\begin{split} & \operatorname{consCh}: \{F: \operatorname{Container} \_ - \} \{X: \operatorname{Set} \} \\ & (c: \llbracket F \rrbracket X \to X) \to \operatorname{Church} F \to X \\ & \operatorname{consCh} c \ (\operatorname{Ch} g) = g \ c \\ & \operatorname{cons}: \{F: \operatorname{Container} \_ - \} \{X: \operatorname{Set} \} \\ & (c: \llbracket F \rrbracket X \to X) \to \mu \ F \to X \\ & \operatorname{cons} c = \operatorname{consCh} c \circ \operatorname{toCh} \\ & \operatorname{eqCons}: \{F: \operatorname{Container} \_ - \} \{X: \operatorname{Set} \} \\ & \{c: \llbracket F \rrbracket X \to X\} \to \operatorname{cons} c \equiv \|c\| \\ & \operatorname{eqCons} = \operatorname{refl} \end{split}
```

**Proof obligations** In Harper (2011)'s work, five proofs proofs are given for Church encodings. These are formalized in this module.

```
module agda.church.proofs where
```

The first proof proves that from Ch o to Ch = id, using the reflection law:

The second proof is similar to the first, but it proves the composition in the other direction to Ch of from Ch = id. This proofs leverages parametricity as described by Wadler (1989). It postulates the free theorem of the function g: for all A. (F A -> A) -> A, to prove that "applying g to b and then passing the result to h, is the same as just folding c over the datatype" (Harper, 2011):

```
(h:B\to C)(g:\{X:\mathsf{Set}\}\to (\llbracket F\rrbracket X\to X)\to X)\to
                      h \circ b \equiv c \circ \mathsf{map} \ h \to h \ (g \ b) \equiv g \ c
fold-invariance : \{F : \mathsf{Container} \ \mathsf{0}\ell \ \mathsf{0}\ell\}\{Y : \mathsf{Set}\}
                       (g: \{X: \mathsf{Set}\} 	o (\llbracket F \rrbracket X 	o X) 	o X)(a: \llbracket F \rrbracket Y 	o Y) 	o
                       (a)(g \text{ in'}) \equiv g a
fold-invariance g a = free (a) g refl
to-from-id : \{F : \mathsf{Container} \ \mathsf{O}\ell \ \mathsf{O}\ell\} \to \mathsf{toCh} \ \circ \ \mathsf{fromCh} \ \{F\} \equiv \mathsf{id}
to-from-id \{F\} = funext \lambda where
  (\mathsf{Ch}\ g) \to \mathsf{begin}
         toCh (fromCh (Ch g))
      \equiv \langle \rangle -- definition of from Ch
         toCh(gin')
      \equiv \langle \rangle -- definition of toCh
         Ch (\lambda \{X\}a \rightarrow (a) (q \text{ in'}))
      \equiv \langle \text{ cong Ch (funexti } \lambda \{Y\} \rightarrow \text{funext (fold-invariance } g)) \rangle
         \mathsf{Ch}\ g
```

The third proof shows church-encoded functions constitute an implementation for the consumer functions being replaced. The proof is proved via reflexivity, but Harper (2011)'s original proof steps are included here for completeness:

```
\begin{array}{l} \mathsf{cons-pres} : \{F : \mathsf{Container} \ 0\ell \ 0\ell \} \{X : \mathsf{Set}\} (b : \llbracket F \rrbracket \ X \to X) \to \\ & \mathsf{consCh} \ b \circ \mathsf{toCh} \equiv ( \lVert b \rVert ) \\ \mathsf{cons-pres} \ \{F\} \ b = \mathsf{funext} \ \lambda \ (x : \mu \ F) \to \mathsf{begin} \\ & \mathsf{consCh} \ b \ (\mathsf{toCh} \ x) \\ \equiv \langle \rangle \ -- \ \ \mathsf{definition} \ \ \mathsf{of} \ \ \mathsf{toCh} \\ & \mathsf{consCh} \ b \ (\mathsf{Ch} \ (\lambda \ a \to ( \lVert a \rVert x)) \\ \equiv \langle \rangle \ -- \ \ \mathsf{function} \ \ \mathsf{application} \\ & (\lambda \ a \to ( \lVert a \rVert x) \ b \\ \equiv \langle \rangle \ -- \ \ \mathsf{function} \ \ \mathsf{application} \\ & ( \lVert b \rVert x \\ \end{array}
```

The fourth proof shows that church-encoded functions constitute an implementation for the producing functions being replaced. The proof is proved via reflexivity, but Harper (2011)'s original proof steps are included here for completeness:

```
 \begin{array}{l} \operatorname{prod-pres}: \ \{F: \operatorname{Container} \ 0\ell \ 0\ell\}\{X: \operatorname{Set}\}(f: \ \{Y: \operatorname{Set}\} \to (\llbracket F \rrbracket \ Y \to Y) \to X \to Y) \to \\ \operatorname{fromCh} \circ \operatorname{prodCh} \ f \equiv f \operatorname{ in'} \\ \operatorname{prod-pres} \ \{F\}\{X\} \ f = \operatorname{funext} \lambda \ (s: X) \to \operatorname{begin} \\ \operatorname{fromCh} \ ((\lambda \ (x: X) \to \operatorname{Ch} \ (\lambda \ a \to f \ a \ x)) \ s) \\ \equiv \langle\rangle \ -- \ \operatorname{function} \ \operatorname{application} \\ \operatorname{fromCh} \ (\operatorname{Ch} \ (\lambda \ a \to f \ a \ s)) \\ \equiv \langle\rangle \ -- \ \operatorname{definition} \ \operatorname{of} \ \operatorname{fromCh} \\ (\lambda \ \{Y: \operatorname{Set}\} \ (a: \llbracket F \rrbracket \ Y \to Y) \to f \ a \ s) \operatorname{in'} \\ \equiv \langle\rangle \ -- \ \operatorname{function} \ \operatorname{application} \\ f \operatorname{in'} \ s \\ \blacksquare \end{array}
```

The fifth, and final proof shows that church-encoded functions constitute an implementation for the conversion functions being replaced. The proof again leverages the free theorem defined earlier:

```
 \begin{array}{l} \operatorname{trans-pres}: \left\{F \; G : \operatorname{Container} \; 0\ell \; 0\ell\right\} \left(f : \left\{X : \operatorname{Set}\right\} \to \left[\!\left[F \;\right]\!\right] X \to \left[\!\left[G \;\right]\!\right] X\right) \to \\ & \operatorname{fromCh} \; \circ \; \operatorname{natTransCh} \; f \; \equiv \left(\!\left[\operatorname{in'} \circ f \;\right]\!\right) \circ \operatorname{fromCh} \\ \operatorname{trans-pres} \; f \; = \; \operatorname{funext} \; \lambda \; \text{where} \\ \left(\operatorname{Ch} \; g\right) \to \operatorname{begin} \\ & \operatorname{fromCh} \; \left(\operatorname{natTransCh} \; f \; (\operatorname{Ch} \; g)\right) \\ \equiv \left\langle\right\rangle \; - \; \operatorname{Function} \; \operatorname{application} \\ & \operatorname{fromCh} \; \left(\operatorname{Ch} \; (\lambda \; a \to g \; (a \circ f))\right) \\ \equiv \left\langle\right\rangle \; - \; \operatorname{Definition} \; \operatorname{of} \; \operatorname{fromCh} \\ & \left(\lambda \; a \to g \; (a \circ f)\right) \; \operatorname{in'} \\ \equiv \left\langle\right\rangle \; - \; \operatorname{Function} \; \operatorname{application} \\ & g \; (\operatorname{in'} \circ f) \\ \equiv \left\langle\right. \; \operatorname{sym} \; \left(\operatorname{fold-invariance} \; g \; (\operatorname{in'} \circ f)\right) \; \right\rangle \\ & \left(\operatorname{in'} \circ f \;\right) \; \left(g \; \operatorname{in'}\right) \\ \equiv \left\langle\right. \; - \; \operatorname{Definition} \; \operatorname{of} \; \operatorname{fromCh} \\ & \left(\operatorname{in'} \circ f \;\right) \; \left(\operatorname{fromCh} \; (\operatorname{Ch} \; g)\right) \\ \end{array}
```

Finally two additional proofs were made to clearly show that any pipeline made using church encodings will fuse down to a simple function application. The first of these two proofs shows that any two composed natural transformation fuse down to one single natural transformation:

```
 \begin{array}{l} \operatorname{natfuse}: \left\{F \ G \ H : \operatorname{Container} \ 0\ell \ 0\ell\right\} \\ \left(nat1: \left\{X : \operatorname{Set}\right\} \to \left[\!\!\left[ F \ \right]\!\!\right] X \to \left[\!\!\left[ G \ \right]\!\!\right] X\right) \to \\ \left(nat2: \left\{X : \operatorname{Set}\right\} \to \left[\!\!\left[ G \ \right]\!\!\right] X \to \left[\!\!\left[ H \ \right]\!\!\right] X\right) \to \\ \operatorname{natTransCh} \ nat2 \circ \operatorname{toCh} \circ \operatorname{fromCh} \circ \operatorname{natTransCh} \ nat1 \equiv \operatorname{natTransCh} \ (nat2 \circ nat1) \\ \operatorname{natTransCh} \ nat2 \circ \operatorname{toCh} \circ \operatorname{fromCh} \circ \operatorname{natTransCh} \ nat1 \\ \equiv \left\langle \operatorname{cong} \left(\lambda \ f \to \operatorname{natTransCh} \ nat2 \circ f \circ \operatorname{natTransCh} \ nat1\right) \operatorname{to-from-id} \right\rangle \\ \operatorname{natTransCh} \ nat2 \circ \operatorname{natTransCh} \ nat1 \\ \equiv \left\langle \operatorname{funext} \left(\lambda \ \operatorname{where} \ (\operatorname{Ch} \ g) \to \operatorname{refl} \right) \right\rangle \\ \operatorname{natTransCh} \ (nat2 \circ nat1) \\ \end{array}
```

The second of these two proofs shows that any pipeline, consisting of a producer, transformer, and consumer function, fuse down to a single function application:

```
 \begin{array}{c} \mathsf{pipefuse} : \{F \ G : \mathsf{Container} \ 0\ell \ 0\ell \} \{X : \mathsf{Set}\} (g : \{Y : \mathsf{Set}\} \to (\llbracket F \rrbracket \ Y \to Y) \to X \to Y) \\ & (nat : \{X : \mathsf{Set}\} \to \llbracket F \rrbracket \ X \to \llbracket G \rrbracket \ X) (c : (\llbracket G \rrbracket \ X \to X)) \to \\ & \mathsf{cons} \ c \circ \mathsf{natTrans} \ nat \circ \mathsf{prod} \ g \equiv g \ (c \circ nat) \\ \mathsf{pipefuse} \ g \ nat \ c = \mathsf{begin} \\ & \mathsf{consCh} \ c \circ \mathsf{toCh} \circ \mathsf{fromCh} \circ \mathsf{natTransCh} \ nat \circ \mathsf{toCh} \circ \mathsf{fromCh} \circ \mathsf{prodCh} \ g \\ \end{array}
```

```
 \begin{array}{l} \equiv \langle \ \mathsf{cong} \ (\lambda \ f \to \mathsf{consCh} \ c \circ f \circ \mathsf{natTransCh} \ nat \circ \mathsf{toCh} \circ \mathsf{fromCh} \circ \mathsf{prodCh} \ g) \ \mathsf{to\text{-}from\text{-}id} \ \rangle \\ & \mathsf{consCh} \ c \circ \mathsf{natTransCh} \ nat \circ \mathsf{toCh} \circ \mathsf{fromCh} \circ \mathsf{prodCh} \ g \\ \equiv \langle \ \mathsf{cong} \ (\lambda \ f \to \mathsf{consCh} \ c \circ \mathsf{natTransCh} \ nat \circ f \circ \mathsf{prodCh} \ g) \ \mathsf{to\text{-}from\text{-}id} \ \rangle \\ & \mathsf{consCh} \ c \circ \mathsf{natTransCh} \ nat \circ \mathsf{prodCh} \ g \\ \equiv \langle \rangle \\ & g \ (c \circ nat) \end{array}
```

**Example:** List fusion In order to clearly see how the Church encodings allows functions to fuse, a datatype was selected such the abstracted function, which have so far been used to prove the needed properties, can be instantiated to demonstrate how the fusion works for functions across a cocrete datatype. In this module is defined: the container, whose interpretation represents the base functor for lists, some convenience functions to make type annotations more readable, a producer function between, a transformation function map, a consumer function sum, and a proof that non-church and church-encoded implementations are equal.

module agda.church.inst.list where

**Datatypes** The index set for the container, as well as the container whose interpretation represents the base funtor for list. Note how ListOp is isomorphis to the datatype 1 + A, I use ListOp instead to make the code more readable:

```
\begin{array}{l} \operatorname{\sf data\ ListOp\ }(A:\operatorname{\sf Set}):\operatorname{\sf Set\ where} \\ \operatorname{\sf nil}:\operatorname{\sf ListOp\ }A \\ \operatorname{\sf cons}:A\to\operatorname{\sf ListOp\ }A \\ \operatorname{\sf F}:(A:\operatorname{\sf Set})\to\operatorname{\sf Container\ }\_\_ \\ \operatorname{\sf F}A=\operatorname{\sf ListOp\ }A\rhd\lambda\ \{\operatorname{\sf nil}\to\operatorname{\sf Fin\ }0\ ; (\operatorname{\sf cons\ }n)\to\operatorname{\sf Fin\ }1\ \} \end{array}
```

Functions representing the run-of-the-mill list datatype and the base functor for list:

```
\begin{array}{l} \mathsf{List} : (A : \mathsf{Set}) \to \mathsf{Set} \\ \mathsf{List} \ A = \mu \ (\mathsf{F} \ A) \\ \mathsf{List'} : (A \ B : \mathsf{Set}) \to \mathsf{Set} \\ \mathsf{List'} \ A \ B = \llbracket \ \mathsf{F} \ A \ \rrbracket \ B \end{array}
```

Helper functions to assist in cleanly writing out instances of lists:

```
\begin{array}{l} [] : \{A:\mathsf{Set}\} \to \mu \; (\mathsf{F} \; A) \\ [] = \mathsf{in'} \; (\mathsf{nil} \; , \; \lambda()) \\ \ldots : \{A:\mathsf{Set}\} \to A \to \mathsf{List} \; A \to \mathsf{List} \; A \\ \ldots \; x \; xs = \mathsf{in'} \; (\mathsf{cons} \; x \; , \; \mathsf{const} \; xs) \\ \\ \mathsf{infixr} \; 20 \; \ldots \end{array}
```

The fold funtion as it would normally be encountered for lists, defined in terms of (\_):

```
fold' : \{A \ X : \mathsf{Set}\}(n : X)(c : A \to X \to X) \to \mathsf{List}\ A \to X fold' \{A\}\{X\}\ n\ c = ((\lambda\{(\mathsf{nil}\ , \ \_) \to n; (\mathsf{cons}\ n\ , \ g) \to c\ n\ (g\ \mathsf{zero})\})
```

**between** The recursion principle b, which when used, represents the between function. It uses b' to assist termination checking:

```
\begin{array}{l} \mathsf{b'}: \{B:\mathsf{Set}\} \to (a:\mathsf{List'} \ \mathbb{N} \ B \to B) \to \mathbb{N} \to \mathbb{N} \to B \\ \mathsf{b'} \ a \ x \ \mathsf{zero} = a \ (\mathsf{nil} \ , \ \lambda()) \\ \mathsf{b'} \ a \ x \ (\mathsf{suc} \ n) = a \ (\mathsf{cons} \ x \ , \ \mathsf{const} \ (\mathsf{b'} \ a \ (\mathsf{suc} \ x) \ n)) \\ \mathsf{b}: \{B:\mathsf{Set}\} \to (a:\mathsf{List'} \ \mathbb{N} \ B \to B) \to \mathbb{N} \times \mathbb{N} \to B \\ \mathsf{b} \ a \ (x \ , \ y) = \mathsf{b'} \ a \ x \ (\mathsf{suc} \ (y \ - x)) \end{array}
```

The functions between1 and between2. The former is defined without a church-encoding, the latter with. A reflexive proof and sanity check is included to show equality:

```
between1 : \mathbb{N} \times \mathbb{N} \to \mathsf{List} \ \mathbb{N}
between2 : \mathbb{N} \times \mathbb{N} \to \mathsf{List} \ \mathbb{N}
between2 : \mathbb{N} \times \mathbb{N} \to \mathsf{List} \ \mathbb{N}
between2 = prod b
eqbetween : between1 \equiv between2
eqbetween = refl
checkbetween : 2 :: 3 :: 4 :: 5 :: 6 :: [] \equiv between2 (2 , 6)
checkbetween = refl
```

map The algebra m, which when used in an algebra, represents the map function:

```
\begin{array}{l} \mathsf{m}: \{A\ B\ C: \mathsf{Set}\}(f:A\to B)\to \mathsf{List'}\ A\ C\to \mathsf{List'}\ B\ C\\ \mathsf{m}\ f\ (\mathsf{nil}\ ,\ \_)=(\mathsf{nil}\ ,\ \lambda())\\ \mathsf{m}\ f\ (\mathsf{cons}\ n\ ,\ l)=(\mathsf{cons}\ (f\ n)\ ,\ l) \end{array}
```

The functions map1 and map2. The former is defined without a church-encoding, the latter with. A reflexive proof and sanity check is included to show equality:

```
\begin{array}{l} \operatorname{map1}: \{A \ B : \operatorname{Set}\}(f : A \to B) \to \operatorname{List} \ A \to \operatorname{List} \ B \\ \operatorname{map1} \ f = ( \operatorname{in'} \circ \operatorname{m} f ) \\ \operatorname{map2}: \{A \ B : \operatorname{Set}\}(f : A \to B) \to \operatorname{List} \ A \to \operatorname{List} \ B \\ \operatorname{map2} \ f = \operatorname{natTrans} \ (\operatorname{m} f) \\ \operatorname{eqmap}: \{f : \mathbb{N} \to \mathbb{N}\} \to \operatorname{map1} f \equiv \operatorname{map2} f \\ \operatorname{eqmap} = \operatorname{refl} \\ \operatorname{checkmap}: (\operatorname{map1} \ (\_+\_2) \ (3 :: 6 :: [])) \equiv 5 :: 8 :: [] \\ \operatorname{checkmap} = \operatorname{refl} \end{array}
```

sum The algebra s, which when used in an algebra, represents the sum function:

```
s : List' \mathbb{N} \mathbb{N} \to \mathbb{N} s (nil , _) = 0 s (cons n , f) = n+f zero
```

The functions sum1 and sum2. The former is defined without a church-encoding, the latter with. A reflexive proof and sanity check is included to show equality:

```
\begin{array}{l} sum1: List \ \mathbb{N} \to \mathbb{N} \\ sum1 = (|s|) \\ sum2: List \ \mathbb{N} \to \mathbb{N} \\ sum2 = consu \ s \\ eqsum: sum1 \equiv sum2 \\ eqsum = refl \\ checksum: sum1 \ (5:: 6:: 7:: []) \equiv 18 \\ checksum = refl \end{array}
```

**equality** The below proof shows the equality between the non-church-endcoded pipeline and the church-encoded pipeline:

```
\begin{array}{l} \operatorname{eq}: \{f: \mathbb{N} \to \mathbb{N}\} \to \operatorname{sum1} \circ \operatorname{map1} f \circ \operatorname{between1} \equiv \operatorname{sum2} \circ \operatorname{map2} f \circ \operatorname{between2} \\ \operatorname{eq}: \{f\} = \operatorname{begin} \\ \quad ( \mid \mathsf{s} \mid ) \circ ( \mid \operatorname{in'} \circ \mathsf{m} f \mid ) \circ \operatorname{b} \operatorname{in'} \\ \equiv \langle \operatorname{cong} \left( \lambda \ g \to ( \mid \mathsf{s} \mid ) \circ ( \mid \operatorname{in'} \circ \mathsf{m} f \mid ) \circ g \right) \left( \operatorname{prod-pres} \, \mathsf{b} \right) \rangle -- \operatorname{reflexive} \\ \quad ( \mid \mathsf{s} \mid ) \circ ( \mid \operatorname{in'} \circ \mathsf{m} f \mid ) \circ \operatorname{fromCh} \circ \operatorname{prodCh} \, \mathsf{b} \\ \equiv \langle \operatorname{cong} \left( \lambda \ f \to ( \mid \mathsf{s} \mid ) \circ f \circ \operatorname{prodCh} \, \mathsf{b} \right) \left( \operatorname{sym} \$ \operatorname{trans-pres} \left( \mathsf{m} f \right) \right) \rangle \\ \quad ( \mid \mathsf{s} \mid ) \circ \operatorname{fromCh} \circ \operatorname{natTransCh} \left( \mathsf{m} f \right) \circ \operatorname{prodCh} \, \mathsf{b} \right) \left( \operatorname{cons-pres} \, \mathsf{s} \right) \rangle -- \operatorname{reflexive} \\ \quad \operatorname{consCh} \, \mathsf{s} \circ \operatorname{toCh} \circ \operatorname{fromCh} \circ \operatorname{natTransCh} \left( \mathsf{m} f \right) \circ \operatorname{prodCh} \, \mathsf{b} \right) \end{array}
```

```
\equiv \langle \text{ cong } (\lambda \ g \to \text{consCh s} \circ \text{toCh} \circ \text{fromCh} \circ \text{natTransCh} \ (\text{m} \ f) \circ g \circ \text{prodCh} \ \text{b)} \ (\text{sym to-from-id}) \ \rangle

#### 3.2.2 Cochurch encodings

This section describes the church-encodings and the proofs needed for the fusion property.

**Definition of Cochurch encodings** This module defines Cochurch encodings and the two conversion functions con and abs, called toCoCh and fromCoCh here, respectively. It also defines the generalized producing, transformation, and consuming functions, as described by Harper (2011). The definition of the CoChurch datatypes is defined slightly differently to how it is initially defined by Harper (2011). Instead an Isomorphic definition is used, whose type is described later on on the same page. The original definition is included as CoChurch'.

```
{-# OPTIONS --guardedness #-} module agda.cochurch.defs where
```

The Cochurch encoding, agian leveraging containers:

The conversion functions:

```
\begin{array}{l} \mathsf{toCoCh}: \{F: \mathsf{Container} \ \mathsf{0}\ell \ \mathsf{0}\ell\} \to \nu \ F \to \mathsf{CoChurch} \ F \\ \mathsf{toCoCh} \ x = \mathsf{CoCh} \ \mathsf{out} \ x \\ \\ \mathsf{fromCoCh}: \{F: \mathsf{Container} \ \mathsf{0}\ell \ \mathsf{0}\ell\} \to \mathsf{CoChurch} \ F \to \nu \ F \\ \mathsf{fromCoCh} \ (\mathsf{CoCh} \ h \ x) = \mathsf{A} \llbracket \ h \ \rrbracket \ x \end{array}
```

The generalized encoded producing, transformation, and consuming functions, alongside the proof that they are equal to the functions they are encoding. First, the producing function, note that this is a generalized version of Svenningsson (2002)'s unfoldr function:

```
\begin{array}{l} \operatorname{prodCoCh}: \{F: \operatorname{Container} \ 0\ell \ 0\ell\} \{Y: \operatorname{Set}\} \to (g: \ Y \to \llbracket \ F \ \rrbracket \ Y) \to Y \to \operatorname{CoChurch} \ F \\ \operatorname{prodCoCh} \ g \ x = \operatorname{CoCh} \ g \ x \\ \\ \operatorname{prod}: \{F: \operatorname{Container} \ 0\ell \ 0\ell\} \{Y: \operatorname{Set}\} \to (g: \ Y \to \llbracket \ F \ \rrbracket \ Y) \to Y \to \nu \ F \\ \operatorname{prod} \ g = \operatorname{fromCoCh} \circ \operatorname{prodCoCh} \ g \\ \\ \operatorname{eqprod}: \{F: \operatorname{Container} \ 0\ell \ 0\ell\} \{Y: \operatorname{Set}\} \{g: (Y \to \llbracket \ F \ \rrbracket \ Y)\} \to \\ \\ \operatorname{prod} \ g \equiv \operatorname{A} \llbracket \ g \ \rrbracket \\ \\ \operatorname{eqprod} = \operatorname{refl} \end{array}
```

Second the transformation function:

```
 \begin{array}{l} \mathsf{natTransCoCh} : \{F \ G : \mathsf{Container} \ 0\ell \ 0\ell \} (nat : \{X : \mathsf{Set}\} \to \llbracket \ F \ \rrbracket \ X \to \llbracket \ G \ \rrbracket \ X) \to \mathsf{CoChurch} \ F \to \mathsf{CoChurch} \ G \\ \mathsf{natTransCoCh} \ n \ (\mathsf{CoCh} \ h \ s) = \mathsf{CoCh} \ (n \circ h) \ s \\ \\ \mathsf{natTrans} : \{F \ G : \mathsf{Container} \ 0\ell \ 0\ell \} (nat : \{X : \mathsf{Set}\} \to \llbracket \ F \ \rrbracket \ X \to \llbracket \ G \ \rrbracket \ X) \to \nu \ F \to \nu \ G \\ \mathsf{natTrans} \ nat = \mathsf{fromCoCh} \ \circ \ \mathsf{natTransCoCh} \ nat \circ \mathsf{toCoCh} \\ \end{array}
```

```
eqNatTrans : \{F \ G : \text{Container } 0\ell \ 0\ell\}\{nat : \{X : \text{Set}\} \to \llbracket \ F \ \rrbracket \ X \to \llbracket \ G \ \rrbracket \ X\} \to natTrans \ nat \equiv A\llbracket \ nat \circ \text{out } \rrbracket  eqNatTrans = refl
```

Third the consuming function, note that this a is a generalized version of Svenningsson (2002)'s destroy function:

```
 \begin{split} &\mathsf{consCoCh} : \{F : \mathsf{Container} \ 0\ell \ 0\ell\} \{Y : \mathsf{Set}\} \to (c : \{S : \mathsf{Set}\} \to (S \to \llbracket F \rrbracket \ S) \to S \to Y) \to \mathsf{CoChurch} \ F \to Y \\ &\mathsf{consCoCh} \ c \ (\mathsf{CoCh} \ h \ s) = c \ h \ s \\ &\mathsf{cons} : \{F : \mathsf{Container} \ 0\ell \ 0\ell\} \{Y : \mathsf{Set}\} \to (c : \{S : \mathsf{Set}\} \to (S \to \llbracket F \rrbracket \ S) \to S \to Y) \to \nu \ F \to Y \\ &\mathsf{cons} \ c = \mathsf{consCoCh} \ c \circ \mathsf{toCoCh} \\ &\mathsf{eqcons} : \{F : \mathsf{Container} \ 0\ell \ 0\ell\} \{X : \mathsf{Set}\} \{c : \{S : \mathsf{Set}\} \to (S \to \llbracket F \rrbracket \ S) \to S \to X\} \to \\ &\mathsf{cons} \ c \equiv c \ \mathsf{out} \\ &\mathsf{eqcons} = \mathsf{refl} \end{split}
```

The original CoChurch definition is included here for completeness' sake, but it is note used elsewhere in the code.

```
data CoChurch' (F: \mathsf{Container} \ 0\ell \ 0\ell): \mathsf{Set}_1 \ \mathsf{where} cochurch: (\exists \ \lambda \ S \to (S \to \llbracket \ F \ \rrbracket \ S) \times S) \to \mathsf{CoChurch'} \ F
```

A mapping from CoChurch' to CoChurch and back is provided as well as a proof that their compositions are equal to the identity function, thereby proving isomorphism:

```
 \begin{split} &\mathsf{toConv}: \{F: \mathsf{Container} \ \_ \ \} \to \mathsf{CoChurch}' \ F \to \mathsf{CoChurch} \ F \\ &\mathsf{toConv} \ (\mathsf{cochurch} \ (S \ , \ (h \ , \ x))) = \mathsf{CoCh} \ \{\_\} \{S\} \ h \ x \\ &\mathsf{fromConv}: \{F: \mathsf{Container} \ \_ \ \} \to \mathsf{CoChurch} \ F \to \mathsf{CoChurch}' \ F \\ &\mathsf{fromConv} \ (\mathsf{CoCh} \ \{X\} \ h \ x) = \mathsf{cochurch} \ ((X \ , \ h \ , x)) \\ &\mathsf{to-from-conv-id}: \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \to \mathsf{toConv} \ \circ \ \mathsf{fromConv} \ \{F\} \equiv \mathsf{id} \\ &\mathsf{to-from-conv-id}: \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \to \mathsf{fromConv} \ \circ \ \mathsf{toConv} \ \{F\} \equiv \mathsf{id} \\ &\mathsf{from-to-conv-id}: \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \to \mathsf{fromConv} \ \circ \ \mathsf{toConv} \ \{F\} \equiv \mathsf{id} \\ &\mathsf{from-to-conv-id}: \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \to \mathsf{fromConv} \ \circ \ \mathsf{toConv} \ \{F\} \equiv \mathsf{id} \\ &\mathsf{from-to-conv-id}: \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \to \mathsf{fromConv} \ \circ \ \mathsf{toConv} \ \{F\} \equiv \mathsf{id} \\ &\mathsf{from-to-conv-id}: \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \to \mathsf{fromConv} \ \circ \ \mathsf{toConv} \ \{F\} \equiv \mathsf{id} \\ &\mathsf{from-to-conv-id}: \{F: \mathsf{Container} \ 0\ell \ 0\ell\} \to \mathsf{fromConv} \ \circ \ \mathsf{toConv} \ \circ \ \mathsf{
```

**Proof obligations** As with Church encodings, in Harper (2011)'s work, five proof obligations needed to be satisfied. These are formalized in this module.

```
module agda.cochurch.proofs where
```

The first proof proves that fromCoCh o toCh = id, using the reflection law:

The second proof is similar to the first, but it proves the composition in the other direction to CoCh ofrom CoCh = id. This proof leverages the parametricity as described by Wadler (1989). It postulates the free theorem of the function g for a fixed Y f:  $\forall X \rightarrow (X \rightarrow F X) \rightarrow X \rightarrow Y$ , to prove that "unfolding a Cochurch-encoded structure and then re-encoding it yields an equivalent structure" Harper (2011):

```
postulate free : \{F : \text{Container } 0\ell \ 0\ell\}
                            \{C\ D: \mathsf{Set}\} \{Y: \mathsf{Set}_1\} \{c:\ C 	o \llbracket\ F\ \rrbracket\ C\} \{d:\ D 	o \llbracket\ F\ \rrbracket\ D\}
                           (h: C 	o D)(f: \{X: \mathsf{Set}\} 	o (X 	o \llbracket F \rrbracket X) 	o X 	o Y) 	o
                           \mathsf{map}\ h \mathrel{\circ} c \equiv d \mathrel{\circ} h \mathrel{\rightarrow} f\ c \equiv f\ d \mathrel{\circ} h
                           -- TODO: Do D and Y need to be the same thing? This may be a cop-out...
unfold-invariance : \{F : \mathsf{Container} \ \mathsf{0}\ell \ \mathsf{0}\ell\}\{Y : \mathsf{Set}\}
                                (c: Y \rightarrow \llbracket F \rrbracket Y) \rightarrow
                                CoCh \ c \equiv (CoCh \ out) \circ A \llbracket \ c \ \rrbracket
unfold-invariance c = \text{free A} \llbracket c \rrbracket CoCh refl
to-from-id : \{F : \mathsf{Container} \ \mathsf{O}\ell \ \mathsf{O}\ell\} \to \mathsf{toCoCh} \ \circ \ \mathsf{fromCoCh} \ \{F\} \equiv \mathsf{id}
to-from-id = funext \lambda where
   (CoCh \ c \ x) \rightarrow begin
          toCoCh (fromCoCh (CoCh c(x))
       \equiv \langle \rangle -- definition of from Ch
          toCoCh (A\llbracket c \rrbracket x)
       \equiv \langle \rangle -- definition of toCh
          CoCh out (A \llbracket c \rrbracket x)
       \equiv \langle \rangle -- composition
          (CoCh out \circ A\llbracket c \rrbracket) x
       \equiv \langle \text{ cong } (\lambda f \rightarrow f x) \text{ (sym $ unfold-invariance } c) \rangle
```

The third proof shows that cochurch-encoded functions constitute an implementation for the producing functions being replaced. The proof is proved via reflexivity, but Harper (2011)'s original proof steps are included here for completeness:

```
\begin{array}{l} \operatorname{prod-pres}: \ \{F: \operatorname{Container} \ 0\ell \ 0\ell \} \{X: \operatorname{Set}\} (c: X \to \llbracket \ F \ \rrbracket \ X) \to \\ \operatorname{fromCoCh} \circ \operatorname{prodCoCh} \ c \equiv \operatorname{A} \llbracket \ c \ \rrbracket \\ \operatorname{prod-pres} \ c = \operatorname{funext} \ \lambda \ x \to \operatorname{begin} \\ \operatorname{fromCoCh} \ ((\lambda \ s \to \operatorname{CoCh} \ c \ s) \ x) \\ \equiv \langle \rangle \ -- \ \operatorname{function} \ \operatorname{application} \\ \operatorname{fromCoCh} \ (\operatorname{CoCh} \ c \ x) \\ \equiv \langle \rangle \ -- \ \operatorname{definition} \ \operatorname{of} \ \operatorname{toCh} \\ \operatorname{A} \llbracket \ c \ \rrbracket \ x \\ \end{array}
```

The fourth proof shows that cochurch-encoded functions constitute an implementation for the consuming functions being replaced. The proof is proved via reflexivity, but Harper (2011)'s original proof steps are included here for completeness:

```
\begin{array}{l} \mathsf{cons\text{-}pres} : \{F : \mathsf{Container} \ 0\ell \ 0\ell \} \{X : \mathsf{Set}\} \to (f : \{Y : \mathsf{Set}\} \to (Y \to \llbracket \ F \ \rrbracket \ Y) \to Y \to X) \to \\ & \mathsf{cons\mathsf{CoCh}} \ f \circ \mathsf{to\mathsf{CoCh}} \equiv f \ \mathsf{out} \\ \mathsf{cons\text{-}pres} \ f = \mathsf{funext} \ \lambda \ x \to \mathsf{begin} \\ & \mathsf{cons\mathsf{CoCh}} \ f \ (\mathsf{to\mathsf{CoCh}} \ x) \\ \equiv \langle \rangle \ -- \ \mathsf{definition} \ \mathsf{of} \ \mathsf{to\mathsf{CoCh}} \\ & \mathsf{cons\mathsf{CoCh}} \ f \ (\mathsf{CoCh} \ \mathsf{out} \ x) \\ \equiv \langle \rangle \ -- \ \mathsf{function} \ \mathsf{application} \\ & f \ \mathsf{out} \ x \\ \end{array}
```

The fifth, and final proof shows that cochurch-encoded functions constitute an implementation for the consuming functions being replaced. The proof leverages the categorical fusion property and the naturality of **f**:

```
-- PAGE 52 - Proof 5
valid-hom : \{F \mid G : \mathsf{Container} \mid \mathsf{0}\ell \mid \mathsf{0}\ell\}\{X : \mathsf{Set}\}(h : X \to \llbracket \mid F \mid \rrbracket \mid X)
                        (f: \{X: \mathsf{Set}\} \to \llbracket \ F \ \rrbracket \ X \to \llbracket \ G \ \rrbracket \ X)(nat: \ \forall \ \{X: \mathsf{Set}\}(g: X \to \nu \ F) \to \mathsf{map} \ g \circ f \equiv f \circ \mathsf{map} \ g) \to \emptyset
                       \mathsf{map}\;\mathsf{A}\llbracket\;h\;\rrbracket\circ f\circ h\equiv f\circ\mathsf{out}\circ\mathsf{A}\llbracket\;h\;\rrbracket
valid-hom h f nat = begin
        (\mathsf{map}\ \mathsf{A}\llbracket\ h\ \rrbracket\circ f)\circ h
    \equiv \langle \mathsf{cong} \; (\lambda \; f \to f \circ h) \; (\mathit{nat} \; \mathsf{A} \llbracket \; h \; \rrbracket) \; \rangle
        (f \circ \mathsf{map} \ \mathsf{A} \llbracket \ h \ \rrbracket) \circ h
    \equiv \langle \rangle -- dfn of A[_]
        f \circ \mathsf{out} \circ \mathsf{A} \llbracket \ h \ \rrbracket
\mathsf{trans\text{-}pres}: \{F \ G : \mathsf{Container} \ \mathsf{0}\ell \ \mathsf{0}\ell \} \{X : \mathsf{Set}\} (h : X \to \llbracket F \rrbracket X) \ (f : \{X : \mathsf{Set}\} \to \llbracket F \rrbracket X \to \llbracket G \rrbracket X) \}
                       (\mathit{nat}: \{X: \mathsf{Set}\}(g: X 	o 
u F) 	o \mathsf{map} \; g \circ f \equiv f \circ \mathsf{map} \; g) 	o
                       \mathsf{fromCoCh} \, \circ \, \mathsf{natTransCoCh} \, f \equiv \mathsf{A} \llbracket \, f \, \circ \, \mathsf{out} \, \rrbracket \, \circ \, \mathsf{fromCoCh}
trans-pres h f nat = \text{funext } \lambda \text{ where}
    (CoCh \ h \ x) \rightarrow begin
            fromCoCh (natTransCoCh f (CoCh h x))
        \equiv \langle \rangle -- Function application
           fromCoCh (CoCh (f \circ h) x)
        \equiv \langle \rangle -- Definition of from Ch
            A \llbracket f \circ h \rrbracket x
        \equiv \langle \text{ cong-app (fusion A} \parallel h \parallel \text{ (sym (valid-hom } h f nat))) x \rangle -- \text{ Can I remove the fusion prop?}
           A \llbracket f \circ \text{out} \rrbracket (A \llbracket h \rrbracket x)
        \equiv \langle \rangle -- This step is missing from the paper, but mirrors the step taken on the Church-side.
           A \parallel f \circ \text{out} \parallel (\text{fromCoCh} (\text{CoCh } h x))
```

Finally two additional proofs were made to clearly show that any pipeline made using cochurch encodings will fuse down to a simple function application. The first of these two proofs shows that any two composed natural transformation fuse down to one single natural transformation:

```
 \begin{array}{l} \mathsf{natfuse} : \{F \ G \ H : \mathsf{Container} \ 0\ell \ 0\ell \} \\ & (nat1 : \{X : \mathsf{Set}\} \to \llbracket F \ \rrbracket \ X \to \llbracket G \ \rrbracket \ X) \to \\ & (nat2 : \{X : \mathsf{Set}\} \to \llbracket G \ \rrbracket \ X \to \llbracket H \ \rrbracket \ X) \to \\ & \mathsf{natTransCoCh} \ nat2 \circ \mathsf{toCoCh} \circ \mathsf{fromCoCh} \circ \mathsf{natTransCoCh} \ nat1 \equiv \mathsf{natTransCoCh} \ (nat2 \circ nat1) \\ \mathsf{natfuse} \ nat1 \ nat2 = \mathsf{begin} \\ & \mathsf{natTransCoCh} \ nat2 \circ \mathsf{toCoCh} \circ \mathsf{fromCoCh} \circ \mathsf{natTransCoCh} \ nat1 \\ & \equiv \langle \ \mathsf{cong} \ (\lambda \ f \to \mathsf{natTransCoCh} \ nat2 \circ f \circ \mathsf{natTransCoCh} \ nat1) \ \mathsf{to-from-id} \ \rangle \\ & \mathsf{natTransCoCh} \ nat2 \circ \mathsf{natTransCoCh} \ nat1 \\ & \equiv \langle \ \mathsf{funext} \ (\lambda \ \mathsf{where} \ (\mathsf{CoCh} \ g \ s) \to \mathsf{refl}) \ \rangle \\ & \mathsf{natTransCoCh} \ (nat2 \circ nat1) \\ & \blacksquare \end{array}
```

The second of these two proofs shows that any pipeline, consisting of a producer, transformer, and consumer function, fuse down to a single function application:

```
\begin{aligned} & \text{pipefuse} : \{F \ G : \text{Container } 0\ell \ 0\ell \} \{X : \text{Set}\} (c : X \to \llbracket F \rrbracket \ X) \\ & \quad (nat : \{X : \text{Set}\} \to \llbracket F \rrbracket \ X \to \llbracket G \rrbracket \ X) \to \\ & \quad (f : \{Y : \text{Set}\} \to (Y \to \llbracket G \rrbracket \ Y) \to Y \to X) \to \\ & \quad \text{cons } f \circ \text{natTrans } nat \circ \text{prod } c \equiv f \ (nat \circ c) \end{aligned} \\ & \quad \text{pipefuse } c \ nat \ f = \text{begin} \\ & \quad \text{consCoCh } f \circ \text{toCoCh} \circ \text{fromCoCh} \circ \text{natTransCoCh } nat \circ \text{toCoCh} \circ \text{fromCoCh} \circ \text{prodCoCh } c \end{aligned} \\ & \quad \equiv \langle \text{cong } (\lambda \ g \to \text{consCoCh } f \circ g \circ \text{natTransCoCh } nat \circ \text{toCoCh} \circ \text{fromCoCh} \circ \text{prodCoCh } c) \text{ to-from-id } \rangle \\ & \quad \text{consCoCh } f \circ \text{natTransCoCh } nat \circ \text{toCoCh} \circ \text{fromCoCh} \circ \text{prodCoCh } c \rangle \text{ to-from-id } \rangle \\ & \quad \text{consCoCh } f \circ \text{natTransCoCh } nat \circ \text{prodCoCh } c \rangle \\ & \quad \equiv \langle \text{cong } (\lambda \ g \to \text{consCoCh } f \circ \text{natTransCoCh } nat \circ \text{prodCoCh } c) \\ & \quad \equiv \langle \rangle \\ & \quad f \ (nat \circ c) \end{aligned}
```

**Example: List fusion** In order to clearly see how the Cochurch encodings allows functions to fuse, a datatype was selected such the abstracted function, which have so far been used to prove the needed properties, can be instantiated to demonstrate how the fusion works for functions across a cocrete datatype. In this module is defined: the container, whose interpretation represents the base functor for lists, some convenience functions to make type annotations more readable, a producer function between, a transformation function map, a consumer function sum, and a proof that non-cochurch and cochurch-encoded implementations are equal.

**Datatypes** The index set for the container, as well as the container whose interpretation represents the base funtor for list. Note how ListOp is isomorphis to the datatype 1 + A, I use ListOp instead to make the code more readable:

```
\begin{array}{l} \operatorname{\sf data\ ListOp\ }(A:\operatorname{\sf Set}):\operatorname{\sf Set\ where} \\ \operatorname{\sf nil}:\operatorname{\sf ListOp\ }A \\ \operatorname{\sf cons}:A\to\operatorname{\sf ListOp\ }A \\ \operatorname{\sf F}:(A:\operatorname{\sf Set})\to\operatorname{\sf Container\ }0\ell\ 0\ell \\ \operatorname{\sf F} A=\operatorname{\sf ListOp\ }A\rhd\lambda\ \{\ \operatorname{\sf nil}\to\operatorname{\sf Fin\ }0\ ;\ (\operatorname{\sf cons\ }n)\to\operatorname{\sf Fin\ }1\ \} \end{array}
```

Functions representing the run-of-the-mill (potentially infinite) list datatype and the base functor for list:

```
\begin{array}{l} \mathsf{List} : (A : \mathsf{Set}) \to \mathsf{Set} \\ \mathsf{List} \ A = \nu \ (\mathsf{F} \ A) \\ \mathsf{List'} : (A \ B : \mathsf{Set}) \to \mathsf{Set} \\ \mathsf{List'} \ A \ B = \llbracket \ \mathsf{F} \ A \ \rrbracket \ B \end{array}
```

Helper functions to assist in cleanly writing out instances of lists:

```
\begin{tabular}{ll} []: \{A: \mathsf{Set}\} \to \mathsf{List}\ A \\ \mathsf{head}\ [] = \mathsf{nil} \\ \mathsf{tail}\ [] = \lambda() \\ \bot \bot \colon \{A: \mathsf{Set}\} \to A \to \mathsf{List}\ A \to \mathsf{List}\ A \\ \mathsf{head}\ (x::xs) = \mathsf{cons}\ x \\ \mathsf{tail}\ (x::xs) = \mathsf{const}\ xs \\ \mathsf{infixr}\ 20\ \bot \bot \bot \\ \end{tabular}
```

The unfold funtion as it would normally be encountered for lists, defined in terms of [ ] : ]:

```
\begin{array}{l} \operatorname{mapping}: \{A\ X: \mathsf{Set}\} \to (f: X \to \top \uplus (A \times X)) \to (X \to \mathsf{List'}\ A\ X) \\ \operatorname{mapping}\ f\ x & \operatorname{with}\ f\ x \\ \operatorname{mapping}\ f\ x - (\operatorname{inj}_1\ \operatorname{tt}) = (\operatorname{nil}\ ,\ \lambda()) \\ \operatorname{mapping}\ f\ x - (\operatorname{inj}_2\ (a\ ,\ x')) = (\operatorname{cons}\ a\ ,\ \operatorname{const}\ x') \\ \operatorname{unfold'}: \{F: \mathsf{Container}\ 0\ell\ 0\ell\}\{A\ X: \mathsf{Set}\}(f: X \to \top \uplus (A \times X)) \to X \to \mathsf{List}\ A \\ \operatorname{unfold'}\ \{A\}\{X\}\ f = \mathsf{A}[\![\ \mathsf{mapping}\ f\ ]\!] \end{array}
```

**between** The recursion principle b, which when used, represents the between function. It uses b' to assist termination checking:

```
\begin{array}{l} \mathsf{b'}: \mathbb{N} \times \mathbb{N} \to \mathsf{List'} \ \mathbb{N} \ (\mathbb{N} \times \mathbb{N}) \\ \mathsf{b'} \ (x \ , \, \mathsf{zero}) = (\mathsf{nil} \ , \, \lambda()) \\ \mathsf{b'} \ (x \ , \, \mathsf{suc} \ n) = (\mathsf{cons} \ x \ , \, \mathsf{const} \ (\mathsf{suc} \ x \ , \, n)) \\ \mathsf{b} : \mathbb{N} \times \mathbb{N} \to \mathsf{List'} \ \mathbb{N} \ (\mathbb{N} \times \mathbb{N}) \\ \mathsf{b} \ (x \ , \, y) = \mathsf{b'} \ (x \ , \, (\mathsf{suc} \ (y \ - x))) \end{array}
```

The functions between1 and between2. The former is defined without a cochurch-encoding, the latter with. A reflexive proof and sanity check (not working currently) is included to show equality:

```
\begin{array}{l} \mathsf{between1} : \, \mathbb{N} \times \mathbb{N} \to \mathsf{List} \,\, \mathbb{N} \\ \mathsf{between1} = \mathsf{A} \llbracket \,\, \mathsf{b} \,\, \rrbracket \end{array}
```

```
\begin{array}{l} between2: \mathbb{N} \times \mathbb{N} \to List \ \mathbb{N} \\ between2 = prod \ b \\ eqbetween: between1 \equiv between2 \\ eqbetween = refl \\ --checkbetween: out \ (2:: 3:: 4:: 5:: 6:: []) \equiv out \ (between2 \ (2, 6)) \\ --checkbetween = refl \end{array}
```

map The coalgebra m, which when used in an algebra, represents the map function:

```
\begin{array}{l} \mathsf{m}: \{A \ B \ C : \mathsf{Set}\}(f:A \to B) \to \mathsf{List'} \ A \ C \to \mathsf{List'} \ B \ C \\ \mathsf{m} \ f \ (\mathsf{nil} \ , \ l) = (\mathsf{nil} \ , \ l) \\ \mathsf{m} \ f \ (\mathsf{cons} \ n \ , \ l) = (\mathsf{cons} \ (f \ n) \ , \ l) \end{array}
```

The functions map1 and map2. The former is defined without a cochurch-encoding, the latter with. A reflexive proof and sanity check (not currently working) is included to show equality:

```
\begin{array}{l} \operatorname{map1}: \{A \ B : \operatorname{Set}\}(f : A \to B) \to \operatorname{List} \ A \to \operatorname{List} \ B \\ \operatorname{map1} \ f = \mathbb{A}[\![ \ \operatorname{m} \ f \circ \operatorname{out} \ ]\!] \\ \operatorname{map2}: \{A \ B : \operatorname{Set}\}(f : A \to B) \to \operatorname{List} \ A \to \operatorname{List} \ B \\ \operatorname{map2} \ f = \operatorname{natTrans} \ (\operatorname{m} \ f) \\ \operatorname{eqmap}: \{f : \mathbb{N} \to \mathbb{N}\} \to \operatorname{map1} \ f \equiv \operatorname{map2} \ f \\ \operatorname{eqmap} = \operatorname{refl} \\ \operatorname{--checkmap}: \operatorname{map1} \ (\_+\_2) \ (3 :: 6 :: []) \equiv 5 :: 8 :: [] \\ \operatorname{--checkmap} = \operatorname{refl} \end{array}
```

sum The coalgebra s, which when used in an algebra, represents the sum function. Note that it is currently set to be non-terminating. A modification to  $\nu$  is likely needed to enable usage of size type for the termination checker to accept this:

The functions sum1 and sum2. The former is defined without a cochurch-encoding, the latter with. A reflexive proof and sanity check (currently not working) is included to show equality:

```
\begin{array}{l} sum1: List \ \mathbb{N} \to \mathbb{N} \\ sum1 = s \ out \\ sum2: List \ \mathbb{N} \to \mathbb{N} \\ sum2 = consu \ s \\ eqsum: sum1 \equiv sum2 \\ eqsum = refl \\ --checksum: sum1 \ (5 :: 6 :: 7 :: []) \equiv 18 \\ --checksum = refl \end{array}
```

**equality** The below proof shows the equality between the non-cochurch-endoded pipeline and the cochurch-encoded pipeline. Note how it is different from the proof for church-encoded pipelines. This is because Harper (2011)'s proof for the proof obligation of natural transformations is different for cochurch encodings than for church encodings. Because of this the first and second proof step for eq in the church-encoded lists is done in one step here:

```
\begin{array}{l} \mathsf{eq}: \{f: \mathbb{N} \to \mathbb{N}\} \to \mathsf{sum1} \circ \mathsf{map1} \ f \circ \mathsf{between1} \equiv \mathsf{sum2} \circ \mathsf{map2} \ f \circ \mathsf{between2} \\ \mathsf{eq} \ \{f\} = \mathsf{begin} \\ \mathsf{s} \ \mathsf{out} \circ \mathsf{A} \llbracket \ \mathsf{m} \ f \circ \mathsf{out} \ \rrbracket \circ \mathsf{A} \llbracket \ \mathsf{b} \ \rrbracket \\ \equiv \langle \ \mathsf{cong} \ (\lambda \ g \to \mathsf{s} \ \mathsf{out} \circ \mathsf{A} \llbracket \ \mathsf{m} \ f \circ \mathsf{out} \ \rrbracket \circ g) \ (\mathsf{prod-pres} \ \mathsf{b}) \ \rangle \end{array}
```

```
s out \circ A[ m f \circ out ]] \circ fromCoCh \circ prodCoCh b \equiv \langle \operatorname{cong}(\lambda \ g \to \operatorname{s} \operatorname{out} \circ g \circ \operatorname{prodCoCh} \operatorname{b}) \operatorname{(sym}(\operatorname{trans-pres} \operatorname{b}(\operatorname{m} f) \ \lambda \ \_ \to \operatorname{funext}(\lambda \ \{(\operatorname{nil}\ ,\ l) \to \operatorname{refl}; \operatorname{(cons}\ n\ ,\ l) \to \operatorname{sout} \circ \operatorname{fromCoCh} \circ \operatorname{natTransCoCh}(\operatorname{m} f) \circ \operatorname{prodCoCh} \operatorname{b}) = \langle \operatorname{cong}(\lambda \ g \to g \circ \operatorname{fromCoCh} \circ \operatorname{natTransCoCh}(\operatorname{m} f) \circ \operatorname{prodCoCh} \operatorname{b}) \operatorname{(cons-pres} \operatorname{s}) \rangle = \langle \operatorname{cong}(\lambda \ g \to \operatorname{consCoCh} \circ \operatorname{fromCoCh} \circ \operatorname{natTransCoCh}(\operatorname{m} f) \circ \operatorname{prodCoCh} \operatorname{b}) \operatorname{(sym} \operatorname{to-from-id}) \rangle = \langle \operatorname{cong}(\lambda \ g \to \operatorname{consCoCh} \circ \operatorname{fromCoCh} \circ \operatorname{natTransCoCh}(\operatorname{m} f) \circ \operatorname{toCoCh} \circ \operatorname{fromCoCh} \circ \operatorname{prodCoCh} \operatorname{b}) = \langle \operatorname{consCoCh} \circ \operatorname{fromCoCh} \circ \operatorname{natTransCoCh}(\operatorname{m} f) \circ \operatorname{toCoCh} \circ \operatorname{prodCoCh} \operatorname{b}) = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod} \operatorname{b} \rangle = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod}(\operatorname{oth} f) = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{prod}(\operatorname{oth} f) = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{oth} f) = \langle \operatorname{consu} \operatorname{s} \circ \operatorname{natTrans}(\operatorname{m} f) \circ \operatorname{oth} f) = \langle \operatorname{consu} \operatorname{nat}(\operatorname{m} f) \circ \operatorname{oth} f) = \langle \operatorname{consu} \operatorname{o
```

## 4 Haskell Optimizations

In Harper (2011)'s work there were still multiple open questions left regarding the exact mechanics of what Church and Cochurch encodings did while making their way through the compiler. Why are Cochurch encodings faster in some pipelines, but slower in others? etc.

In this section I'll describe my work replicating the fused Haskell code of the Harper (2011)'s work and further optimization opportunities that were discovered along the way.

I'll start off with the existing working code, followed by a discussion of the discoveries made throughout the process of writing, replicating, and further optimizing Harper (2011)'s example code.

## 4.1 Replicated Code

#### 4.1.1 Leaf Trees

In this section, the replication of Harper (2011)'s code is described. We start with his motivating example at the begginning of the paper, followed by the 'fused' version that we want the pipeline to become, once compiled:

```
f :: (Int, Int) \rightarrow Int

f = sum1 \circ map1 \ (+1) \circ filter1 \ odd \circ between1

f' :: (Int, Int) \rightarrow Int

f' \ (x, y) = loop \ x

where

loop \ x \mid x > y = 0

| \ otherwise = if odd \ x

then (x+1) + loop \ (x+1)

else loop \ (x+1)
```

**Datatypes** In his paper Harper (2011) implemented his example functions using leaf trees, this is defined as Tree below. Furthermore, the base functor of Tree was defined, as Tree\_, with the recursive positions of the functor turned into a paramater of the datatype:

```
data Tree\ a = Empty\ |\ Leaf\ a\ |\ Fork\ (Tree\ a)\ (Tree\ a) data Tree\_a\ b = Empty\_|\ Leaf\_a\ |\ Fork\_b\ b
```

**Church-encoding** The Church encoding of the Tree datatype is defined, using the base functor:

```
data TreeCh \ a = TreeCh \ (\forall \ b \circ (Tree\_a \ b \rightarrow b) \rightarrow b)
```

Next, the conversion functions toCh and fromCh are defined, using two auxillary functions fold and in':

```
to Ch:: Tree a \to TreeCh a
to Ch t = TreeCh (\lambda a \to fold\ a\ t)
fold:: (Tree_a b \to b) \to Tree a \to b
fold a Empty = a\ Empty_-
fold a (Leaf x) = a (Leaf_x)
```

```
fold a (Fork l\ r) = a (Fork_ (fold a l)

(fold a r))

from Ch:: Tree Ch a \to Tree a

from Ch (Tree Ch fold) = fold in'

in':: Tree_a (Tree a) \to Tree a

in' Empty_= Empty

in' (Leaf_x) = Leaf x

in' (Fork_l r) = Fork l\ r
```

From here, the fusion rule is defined using a RULES pragma. Along with a couple of other rules, this core construct is responsible for doing the actual 'fusion'. The INLINE pragmas are also included, to delay any inlining of the toCh/fromCh functions to the latest possible moment, maximising the opportunity for fusion throughout the compilation process:

```
{-# RULES "toCh/fromCh fusion" for
all x. toCh (fromCh x) = x #-} 
{-# INLINE [0] toCh #-} 
{-# INLINE [0] fromCh #-}
```

A generalized natural transformation function is defined:

```
natCh :: (\forall \ c \circ Tree\_a \ c \rightarrow Tree\_b \ c) \rightarrow TreeCh \ a \rightarrow TreeCh \ b

natCh \ f \ (TreeCh \ g) = TreeCh \ (\lambda a \rightarrow g \ (a \circ f))
```

**Cochurch-encoding** Conversely, the cochurch encoding is defined, again using the base functor for Tree:

```
data TreeCoCh \ a = \forall \ s \circ TreeCoCh \ (s \to Tree\_a \ s) \ s
```

Next, the conversion functions to CoCh and from CoCh are again defined, using two auxillary functions out and unfold:

```
toCoCh :: Tree \ a \to TreeCoCh \ a
toCoCh = TreeCoCh \ out
out \ Empty = Empty\_
out \ (Leaf \ a) = Leaf\_a
out \ (Fork \ l \ r) = Fork\_l \ r
fromCoCh :: TreeCoCh \ a \to Tree \ a
fromCoCh \ (TreeCoCh \ h \ s) = unfold \ h \ s
unfold \ h \ s = \mathbf{case} \ h \ s \ \mathbf{of}
Empty\_ \to Empty
Leaf\_a \to Leaf \ a
Fork\_sl \ sr \to Fork \ (unfold \ h \ sl) \ (unfold \ h \ sr)
```

Similar to Church-encodings, the proper pragmas are included to enable fusion:

```
{-# RULES "toCh/fromCh fusion" for
all x. toCoCh (fromCoCh x) = x #-} 
{-# INLINE [0] toCoCh #-} 
{-# INLINE [0] fromCoCh #-}
```

A generalized natural transformation function is defined:

```
natCoCh :: (\forall c \circ Tree\_a \ c \rightarrow Tree\_b \ c) \rightarrow TreeCoCh \ a \rightarrow TreeCoCh \ b

natCoCh \ f \ (TreeCoCh \ h \ s) = TreeCoCh \ (f \circ h) \ s
```

Between Three between functions are implemented: One regular, one church-encoded, and one cochurch encoded. Note how all three final functions are accompanied by an INLINE pragma. This inlining enables pairs of toCh o fromCh to be revealed to the compiler for fusion. The regular one is implemented recursively in a fashion appropriate for leaf trees:

```
between1 :: (Int, Int) \rightarrow Tree\ Int
between1 (x, y) = \mathbf{case}\ compare\ x\ y\ \mathbf{of}
GT \rightarrow Empty
EQ \rightarrow Leaf\ x
LT \rightarrow Fork\ (between1\ (x, mid))
(between1\ (mid+1, y))
where mid = (x + y) \ 'div'\ 2
```

The church-encoded version leverages the implementation of a recursion principle **b** for the between function of leaf trees:

```
b :: (\mathit{Tree\_Int}\ b \to b) \to (\mathit{Int}, \mathit{Int}) \to b
b \ a \ (x,y) = \mathbf{case}\ \mathit{compare}\ x\ y\ \mathbf{of}
\mathit{GT} \to a\ \mathit{Empty\_}
\mathit{EQ} \to a\ (\mathit{Leaf\_x})
\mathit{LT} \to a\ (\mathit{Fork\_}(b\ a\ (x,mid))
(b\ a\ (mid+1,y)))
\mathbf{where}\ \mathit{mid} = (x+y)\ '\mathit{div}\ '2
\mathit{betweenCh} :: (\mathit{Int}, \mathit{Int}) \to \mathit{TreeCh}\ \mathit{Int}
\mathit{betweenCh} :: (\mathit{Int}, \mathit{Int}) \to \mathit{TreeCh}\ \mathit{Int}
\mathit{between2} :: (\mathit{Int}, \mathit{Int}) \to \mathit{Tree}\ \mathit{Int}
\mathit{between2} = \mathit{fromCh} \circ \mathit{betweenCh}
\{-\#\ \mathit{INLINE}\ \mathit{between2}\ \#-\}
```

The cochurch-encoded version leverages the implementation of a coalgebra **h** for the between function of leaf trees:

```
h :: (Int, Int) \rightarrow Tree\_Int \ (Int, Int)
h (x, y) = \mathbf{case} \ compare \ x \ y \ \mathbf{of}
GT \rightarrow Empty\_
EQ \rightarrow Leaf\_x
LT \rightarrow Fork\_(x, mid) \ (mid + 1, y)
\mathbf{where} \ mid = (x + y) \ 'div' \ 2
between 3 :: (Int, Int) \rightarrow Tree \ Int
between 3 = from CoCh \circ Tree CoCh \ h
\{-\# \ INLINE \ between 3 \ \#-\}
```

**Filter** Again three versions, similar to between. The regular implementation is as to be expected, leveraging an implementation of append:

```
filter1 :: (a \rightarrow Bool) \rightarrow Tree \ a \rightarrow Tree \ a
filter1 p \ Empty = Empty
filter1 p \ (Leaf \ a) = \mathbf{if} \ p \ a \ \mathbf{then} \ Leaf \ a \ \mathbf{else} \ Empty
filter1 p \ (Fork \ l \ r) = append1 \ (filter1 \ p \ l) \ (filter1 \ p \ r)
```

While for the (co)church-encoded versions a natural transformation filt is constructured. This is used to both implement both the church and cochurch-encoded function:

```
\begin{array}{l} \mathit{filt} :: (a \to Bool) \to \mathit{Tree\_} \ a \ c \to \mathit{Tree\_} \ a \ c \\ \mathit{filt} \ p \ \mathit{Empty\_} = \mathit{Empty\_} \\ \mathit{filt} \ p \ (\mathit{Leaf\_} x) = \mathbf{if} \ p \ x \ \mathbf{then} \ \mathit{Leaf\_} x \ \mathbf{else} \ \mathit{Empty\_} \\ \mathit{filt} \ p \ (\mathit{Fork\_} \ l \ r) = \mathit{Fork\_} \ l \ r \\ \mathit{filter2} :: (a \to Bool) \to \mathit{Tree} \ a \to \mathit{Tree} \ a \\ \mathit{filter2} \ p = \mathit{fromCh} \circ \mathit{natCh} \ (\mathit{filt} \ p) \circ \mathit{toCh} \\ \{-\# \ \mathsf{INLINE} \ \mathit{filter2} \ \#-\} \\ \mathit{filter3} :: (a \to Bool) \to \mathit{Tree} \ a \to \mathit{Tree} \ a \\ \mathit{filter3} \ p = \mathit{fromCoCh} \circ \mathit{natCoCh} \ (\mathit{filt} \ p) \circ \mathit{toCoCh} \\ \{-\# \ \mathsf{INLINE} \ \mathit{filter3} \ \#-\} \end{array}
```

Map The map function is implemented similarly to filter: A simple implementation for the non-encoded version and a single natural transformation that is leveraged in both the church- and cochurch-encoded versions:

```
\begin{array}{l} \mathit{map1} :: (a \to b) \to \mathit{Tree} \ a \to \mathit{Tree} \ b \\ \mathit{map1} \ f \ \mathit{Empty} = \mathit{Empty} \\ \mathit{map1} \ f \ (\mathit{Leaf} \ a) = \mathit{Leaf} \ (f \ a) \\ \mathit{map1} \ f \ (\mathit{Fork} \ l \ r) = \mathit{append1} \ (\mathit{map1} \ f \ l) \ (\mathit{map1} \ f \ r) \\ \mathit{m} :: (a \to b) \to \mathit{Tree} \_ a \ c \to \mathit{Tree} \_ b \ c \\ \mathit{m} \ f \ \mathit{Empty} \_ = \mathit{Empty} \_ \\ \mathit{m} \ f \ (\mathit{Leaf} \_ a) = \mathit{Leaf} \_ (f \ a) \\ \mathit{m} \ f \ (\mathit{Fork} \_ l \ r) = \mathit{Fork} \_ l \ r \\ \mathit{map2} :: (a \to b) \to \mathit{Tree} \ a \to \mathit{Tree} \ b \\ \mathit{map2} :: (a \to b) \to \mathit{Tree} \ a \to \mathit{Tree} \ b \\ \mathit{map3} :: (a \to b) \to \mathit{Tree} \ a \to \mathit{Tree} \ b \\ \mathit{map3} :: (a \to b) \to \mathit{Tree} \ a \to \mathit{Tree} \ b \\ \mathit{map3} \ f = \mathit{fromCoCh} \circ \mathit{natCoCh} \ (\mathit{m} \ f) \circ \mathit{toCoCh} \\ \{-\# \ \mathsf{INLINE} \ \mathit{map3} \ \#-\} \end{array}
```

**Sum** The sum function is again more interesting, it is again implemented in three different ways: The non-encoded version is again as would normally be expected for leaf trees:

```
sum1 :: Tree \ Int \rightarrow Int

sum1 \ Empty = 0

sum1 \ (Leaf \ x) = x

sum1 \ (Fork \ x \ y) = sum1 \ x + sum1 \ y
```

The church encoded version leverages an alagebra s:

```
s:: Tree\_Int\ Int 	o Int

s\ Empty\_=0

s\ (Leaf\_x)=x

s\ (Fork\_x\ y)=x+y

sumCh:: TreeCh\ Int 	o Int

sumCh\ (TreeCh\ g)=g\ s

sum2:: Tree\ Int 	o Int

sum2=sumCh\circ toCh

\{-\#\ INLINE\ sum2\ \#-\}
```

The cochurch encoding is defined using a coinduction principle. Note that it is possible to implement this function using an accumulator of a list datatype (used like a queue), but it currently does not seem to provide a fused Core AST, for a more expansive discussion on tail-recursive cochurch-encoded pipelines, see 4.2.1:

```
sumCoCh :: TreeCoCh \ Int \rightarrow Int \\ sumCoCh \ (TreeCoCh \ h \ s') = loop \ s' \\ \textbf{where} \ loop \ s = \textbf{case} \ h \ s \ \textbf{of} \\ Empty\_ \rightarrow 0 \\ Leaf\_ x \rightarrow x \\ Fork\_ l \ r \rightarrow loop \ l + loop \ r \\ sum3 :: Tree \ Int \rightarrow Int \\ sum3 = sumCoCh \circ toCoCh \\ \{-\# \ INLINE \ sum3 \ \#-\}
```

**Pipelines** Finally the pipelines, whose performance can be measure or Core representation inspected, are defined below:

```
pipeline1 = sum1 \circ map1 \ (+2) \circ filter1 \ odd \circ between1

pipeline2 = sum2 \circ map2 \ (+2) \circ filter2 \ odd \circ between2

pipeline3 = sum3 \circ map3 \ (+2) \circ filter3 \ odd \circ between3
```

```
sumApp1\ (x,y) = sum1\ (append1\ (between1\ (x,y))\ (between1\ (x,y)))

sumApp2\ (x,y) = sum2\ (append2\ (between2\ (x,y))\ (between2\ (x,y)))

sumApp3\ (x,y) = sum3\ (append3\ (between3\ (x,y))\ (between3\ (x,y)))

input = (1,10000)

main = print\ (pipeline3\ input)
```

#### 4.1.2 Lists

In this section further replication of Harper (2011)'s work is described, but instead of implementing Leaf trees, Lists are implemented.

This was done to see how the descriptions in Harper (2011)'s work generalize and to have a simpler datastructure on which to perform analysis; seeing how and when the fusion works and when it doesn't.

We again start with the datatype descriptions. We use List' instead of List as there is a namespace collision with GHC's List datatype:

```
data List' a = Nil \mid Cons \ a \ (List' \ a)
data List_{-} a \ b = Nil_{-} \mid Cons_{-} a \ b
```

(Co)Church-encodings The church encoding, proper encoding and decoding functions, and fusion pragmas are defined:

```
data ListCh a = ListCh (\forall b \circ (List\_a\ b \to b) \to b) toCh :: List'\ a \to ListCh\ a toCh\ t = ListCh\ (\lambda a \to fold\ a\ t) fold\ :: (List\_a\ b \to b) \to List'\ a \to b fold\ a\ Nil = a\ Nil\_ fold\ a\ (Cons\ x\ xs) = a\ (Cons\_x\ (fold\ a\ xs)) fromCh\ :: ListCh\ a \to List'\ a fromCh\ (ListCh\ fold') = fold'\ in' in':: List\_a\ (List'\ a) \to List'\ a in'\ Nil\_=Nil in'\ (Cons\_x\ xs) = Cons\ x\ xs \{-\#\ RULES\ "toCh/fromCh\ fusion"\ forall\ x.\ toCh\ (fromCh\ x) = x\ \#-\} \{-\#\ INLINE\ [0]\ toCh\ \#-\} \{-\#\ INLINE\ [0]\ fromCh\ \#-\}
```

A generalized natural transformation function is defined:

```
natCh :: (\forall \ c \circ List\_ \ a \ c \to List\_ \ b \ c) \to ListCh \ a \to ListCh \ b \ natCh \ f \ (ListCh \ g) = ListCh \ (\lambda a \to g \ (a \circ f))
```

The cochurch encodings are defined similarly:

```
data ListCoCh a = \forall s \circ ListCoCh (s \to List\_a\ s)\ s toCoCh :: List'\ a \to ListCoCh\ a toCoCh = ListCoCh\ out out :: List'\ a \to List\_a\ (List'\ a) out\ Nil = Nil\_ out\ (Cons\ x\ xs) = Cons\_x\ xs fromCoCh :: ListCoCh\ a \to List'\ a fromCoCh\ (ListCoCh\ a \to List'\ a fromCoCh\ (ListCoCh\ h\ s) = unfold\ h\ s unfold\ :: (b \to List\_a\ b) \to b \to List'\ a unfold\ h\ s = \mathbf{case}\ h\ s\ \mathbf{of} Nil\_\to Nil Cons\_x\ xs \to Cons\ x\ (unfold\ h\ xs) \{-\#\ RULES\ "toCh/fromCh\ fusion"\ forall\ x.\ toCoCh\ (fromCoCh\ x) = x\ \#-\} \{-\#\ INLINE\ [0]\ toCoCh\ \#-\} \{-\#\ INLINE\ [0]\ fromCoCh\ \#-\}
```

A generalized natural transformation function is defined:

```
natCoCh :: (\forall c \circ List\_a \ c \to List\_b \ c) \to ListCoCh \ a \to ListCoCh \ b

natCoCh \ f \ (ListCoCh \ h \ s) = ListCoCh \ (f \circ h) \ s
```

Between The between function is defined in three different fashions: Normally, with the Church-encoding, and with the Cochurch encoding. We leverage INLINE pragmas to make sure that the fusion pragmas can effectively work. For the non-encoded implementation, we simply leverage recursion:

```
\begin{array}{l} between1 :: (Int, Int) \rightarrow List' \ Int \\ between1 \ (x,y) = \mathbf{case} \ x > y \ \mathbf{of} \\ True \rightarrow Nil \\ False \rightarrow Cons \ x \ (between1 \ (x+1,y)) \\ \{\text{-}\# \ INLINE \ between1 \ \#\text{-}} \end{array}
```

For the Church-encoded version we define a recursion principle **b** and use that to define the encoded church function:

```
\begin{array}{l} b:: (List\_Int\ b \to b) \to (Int,Int) \to b \\ b\ a\ (x,y) = \mathbf{case}\ x > y\ \mathbf{of} \\ True \to a\ Nil\_\\ False \to a\ (Cons\_x\ (b\ a\ (x+1,y))) \\ betweenCh:: (Int,Int) \to ListCh\ Int \\ betweenCh\ (x,y) = ListCh\ (\lambda a \to b\ a\ (x,y)) \\ between2:: (Int,Int) \to List'\ Int \\ between2 = fromCh \circ betweenCh \\ \{-\#\ INLINE\ between2\ \#-\} \end{array}
```

For the Cochurch-encoded version we define a coalgebra:

```
between CoCh :: (Int, Int) \rightarrow List\_Int (Int, Int)
between CoCh (x, y) = \mathbf{case} \ x > y of True \rightarrow Nil\_
False \rightarrow Cons\_x \ (x+1, y)
between 3 :: (Int, Int) \rightarrow List' Int
between 3 = from CoCh \circ ListCoCh between CoCh
\{-\# \ INLINE \ between 3 \ \#-\}
```

**Filter** The filter function is, again, implemented in three different ways: In a non-encoded fashion, using a church-encoding, and using a cochurch-encoding. The non-encoded function simply uses recursion:

```
filter1 :: (a \rightarrow Bool) \rightarrow List' \ a \rightarrow List' \ a
filter1 _ Nil = Nil
filter1 p (Cons \ x \ xs) = \mathbf{if} \ p \ x \ \mathbf{then} \ Cons \ x \ (filter1 \ p \ xs) \ \mathbf{else} \ filter1 \ p \ xs
\{-\# \ INLINE \ filter1 \ \#-\}
```

The church-encoded version does **not** leverage an algebra, as is normally done for natural transformations, but instead something else. I.e. the function **a** below is only selectively applied to the resultant subterms (see the **else** case specifically):

```
\begin{array}{l} \mathit{filterCh} :: (a \to Bool) \to \mathit{ListCh} \ a \to \mathit{ListCh} \ a \\ \mathit{filterCh} \ p \ (\mathit{ListCh} \ g) = \mathit{ListCh} \ (\lambda a \to g \ (\lambda \mathbf{case} \\ \mathit{Nil}_- \to a \ \mathit{Nil}_- \\ \mathit{Cons}_- \ x \ s \to \mathbf{if} \ (p \ x) \ \mathbf{then} \ a \ (\mathit{Cons}_- \ x \ ss) \ \mathbf{else} \ ss \\ )) \\ \mathit{filter2} :: (a \to Bool) \to \mathit{List'} \ a \to \mathit{List'} \ a \\ \mathit{filter2} \ p = \mathit{fromCh} \circ \mathit{filterCh} \ p \circ \mathit{toCh} \\ \{-\# \ \mathsf{INLINE} \ \mathit{filter2} \ \#-\} \end{array}
```

For the cochurch-encoding, a natural transformation can be defined, but it is not a simple algebra, instead it is a recursive function. There is existing work, called joint-point optimization that should enable this function to still fully fuse, but it does not at the moment, there are existing issues in GHC's issue tracker that describe this problem:

```
 \begin{array}{c} \textit{filt } p \; h \; s = go \; s \\ & \text{where } go \; s = \mathbf{case} \; h \; s \; \mathbf{of} \\ & Nil_{-} \to Nil_{-} \\ & Cons_{-} \; x \; xs \to \mathbf{if} \; p \; x \; \mathbf{then} \; Cons_{-} \; x \; xs \; \mathbf{else} \; go \; xs \\ \textit{filterCoCh} :: (a \to Bool) \to ListCoCh \; a \to ListCoCh \; a \\ \textit{filterCoCh} \; p \; (ListCoCh \; h \; s) = ListCoCh \; (\textit{filt } p \; h) \; s \\ \textit{filter3} :: (a \to Bool) \to List' \; a \to List' \; a \\ \textit{filter3} \; p = fromCoCh \circ \textit{filterCoCh} \; p \circ toCoCh \\ \{-\# \; \text{INLINE} \; \text{filter3} \; \#-\} \end{array}
```

It is possible to implement filter using a natural transformation, but this requires us to modify the type of the base functor, so we can communicate 'skip' to the datatype, which our corecursion principle can handle accordingly. This technique is called *stream fusion* and is described by Coutts et al. (2007).

Map Contrary to filter, it is possible to implement the map function as a natural transformation. Again three implementations, the latter two of which leverage the defined natural transformation m:

```
\begin{array}{l} map1 :: (a \rightarrow b) \rightarrow List' \ a \rightarrow List' \ b \\ map1 \ \_Nil = Nil \\ map1 \ f \ (Cons \ x \ xs) = Cons \ (f \ x) \ (map1 \ f \ xs) \\ \{-\# \ INLINE \ map1 \ \#-\} \\ m :: (a \rightarrow b) \rightarrow List\_ \ a \ c \rightarrow List\_ \ b \ c \\ m \ f \ (Cons\_ x \ xs) = Cons\_ \ (f \ x) \ xs \\ m \ \_Nil\_ = Nil\_ \\ map2 :: (a \rightarrow b) \rightarrow List' \ a \rightarrow List' \ b \\ map2 \ f = fromCh \circ natCh \ (m \ f) \circ toCh \\ \{-\# \ INLINE \ map2 \ \#-\} \\ map3 \ f = fromCoCh \circ natCoCh \ (m \ f) \circ toCoCh \\ \{-\# \ INLINE \ map3 \ \#-\} \end{array}
```

**Sum** We define our sum function in, *again* three different ways: non-encoded, church-encoded, and cochurch-encoded. The non-encoded leverages simple recursion:

```
sum1 :: List' Int \rightarrow Int

sum1 \ Nil = 0

sum1 \ (Cons \ x \ xs) = x + sum1 \ xs

\{-\# \ INLINE \ sum1 \ \#-\}
```

The church-encoded function leverages an algebra and applies that the existing recursion principle:

```
su :: List_{-} Int Int \rightarrow Int

su \ Nil_{-} = 0

su \ (Cons_{-} x \ y) = x + y

sumCh :: ListCh \ Int \rightarrow Int

sumCh \ (ListCh \ g) = g \ su

sum2 :: List' \ Int \rightarrow Int

sum2 = sumCh \circ toCh

\{-\# \ INLINE \ sum2 \ \#-\}
```

The cochurch-encoded function implements a corecursion principle and applies the existing coalgebra (and input) to it:

```
Cons\_x \ xs \to loopt \ xs \ (x+sum) sumCoCh :: ListCoCh \ Int \to Int sumCoCh \ (ListCoCh \ h \ s) = su' \ h \ s sum3 :: List' \ Int \to Int sum3 = sumCoCh \circ toCoCh \{-\# \ INLINE \ sum3 \ \#-\}
```

Note that two subfunctions are provided to  $\mathfrak{su}$ , the loop and the loopt function. The former function is implement as one would naively expect. The latter, interestingly, is implemented using tail-recursion. Because this loopt function constitutes a corecursion principle, all the algebras (or natural transformations) applied to it, will be inlined in such a way that the resultant function is also tail recursive, in some cases providing a significant speedup! For more details, see the discussion in Section 4.2.1.

## Pipelines and GHC list fusion

```
trodd :: Int \rightarrow Bool
trodd \ n = n \text{ '}rem' \ 2 \equiv 0
 {-# INLINE trodd #-}
pipeline1 = sum1 \circ map1 \ (+2) \circ filter1 \ trodd \circ between1
pipeline2 = sum2 \circ map2 \ (+2) \circ filter2 \ trodd \circ between2
pipeline3 = sum3 \circ map3 \ (+2) \circ filter3 \ trodd \circ between3
pipeline 4 (x, y) = loop x y 0
  where loop z y sum = case z > y of
                             True \rightarrow sum
                             False \rightarrow \mathbf{if} \ trodd \ z
                                         then loop (z + 1) y (sum + z + 2)
                                         else loop (z+1) y sum
between5 :: (Int, Int) \rightarrow [Int]
between5 (x, y) = [x ... y]
 {-# INLINE between5 #-}
filter5 :: (Int \rightarrow Bool) \rightarrow [Int] \rightarrow [Int]
filter5 f xs = build (\lambda c \ n \rightarrow foldr \ (\lambda a \ b \rightarrow \mathbf{if} \ f \ a \ \mathbf{then} \ c \ a \ b \ \mathbf{else} \ b) \ n \ xs)
 {-# INLINE filter5 #-}
map5 :: \forall a \ b \circ (a \rightarrow b) \rightarrow [a] \rightarrow [b]
map5 \ f \ xs = build \ (\lambda c \ n \to foldr \ (\lambda a \ b \to c \ (f \ a) \ b) \ n \ xs)
 {-# INLINE map5 #-}
sum 5 :: [Int] \rightarrow Int
sum5 = foldl' (\lambda a \ b \rightarrow a + b) \ 0
 {-# INLINE sum5 #-}
pipeline5 = sum5 \circ map5 \ (+2) \circ filter5 \ trodd \circ between5
     -- sumApp1 (x, y) = sum1 (append1 (between1 <math>(x, y)) (between1 (x, y)))
     -- sumApp2 (x, y) = sum2 (append2 (between2 (x, y)) (between2 (x, y)))
     -- sumApp3 (x, y) = \text{sum3 (append3 (between3 (x, y)) (between3 (x, y)))}
input :: (Int, Int)
input = (1, 10000)
main :: IO ()
main = print (pipeline5 input)
```

#### 4.2 Discussion of code

#### 4.2.1 Limitations of Church-fusion and perks of stream-fusion

Lack of explanation on Harper (2011)'s part about choice of leaf trees, how in lists, it is not possible to implement filter as a natural transformation.

### 4.2.2 The strength of cochurch encodings: tail recursion

Story of how, through analyzing the core representation and working through and example of the Church and Cochurch encoding by hand enabled the discovery that the corecursion principle ends up being the final function. If this corecursion principle is tail-recursive, so will the final function.

#### 4.2.3 Join point optimization

## 5 Related Works

#### 5.1 Fusion

Initial work on fusion was done my Wadler (1984, 1986, 1990), and was dubbed 'deforestation', referring to the removal of intermediate trees (or lists). The details of the original deforestation work are not relevant to this thesis, but, the weaknesses of the work are described and different techniques proposed by Gill et al. (1993). Gill et al. (1993) describe a technique nowadays called foldr/build fusion, which, when employed, can eliminate most intermediate lists. This technique is described further in Section 2.1.

A converse approach, aptly named the destroy/unfoldr rule, is described by Svenningsson (2002), which describes the converse technique to Gill et al. (1993)'s. A further generalization of this technique, leverages the coinductive list datatype, stream. This technique is called *stream fusion* introduced by Coutts et al. (2007).

(Co)Church encodings Finally, Harper (2011) combined all of these concepts into one paper, called "The Library Writer's Guide to Shortcut Fusion". In it the concept of (Co)Church encodings are described and, pragmatically, how to implement them in Haskell.

## 6 Conclusion and Future Work

#### 6.1 Future Work

- Strengthen Agda's typechecker wrt implicit parameters
- Strengthen Agda's termination checker wrt corecursive datastructures
- Implement (co)church-fused versions of Haskell's library functions.
- Investigate if creating a language that has this fusion built-in natively can be compiled more efficiently
- Look into leveraging parametricity with agda, so no posulate's are needed.
